

# DART\_LAB Tutorial Section 4: Nonlinear and Non-Gaussian Extensions

# Quantile Conserving Ensemble Filters in Observation Space

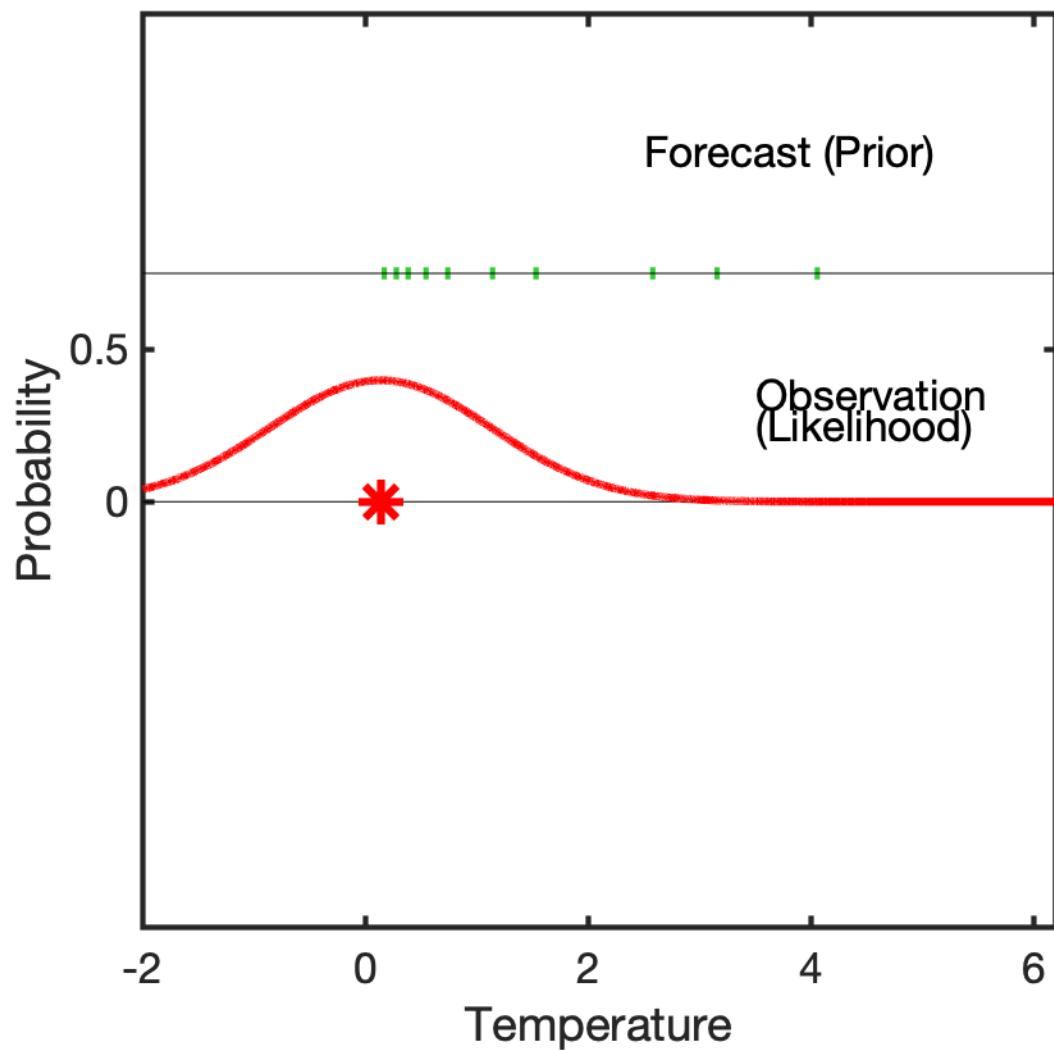

DART now provides nearly general solutions for this step:  
(Anderson, 2022, MWR150, 1061-1074).

# The Mesa Lab: Weather can Impact the Commute

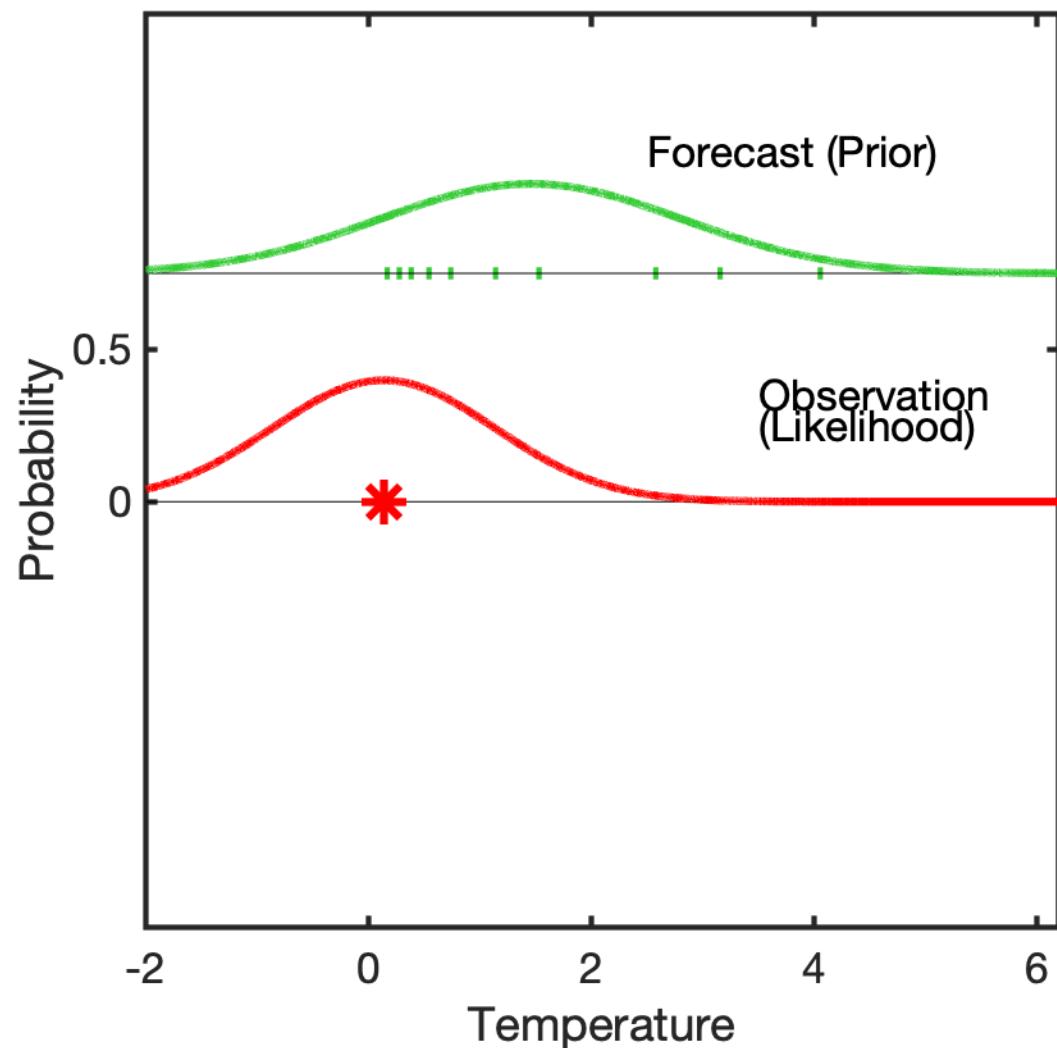

# Should I Worry About Ice Going Down the Hill?

Have 10 forecasts of NCAR temperature.

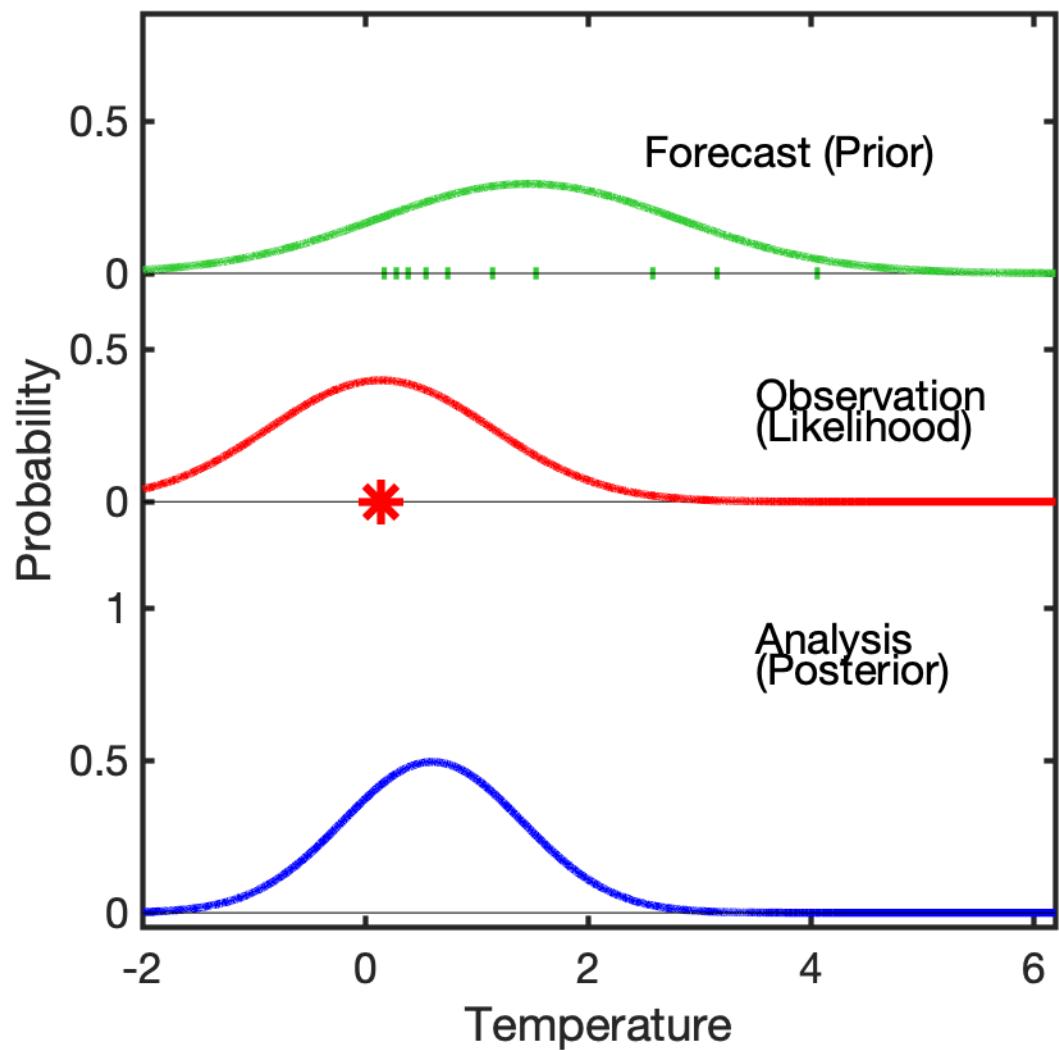

Use Bayes to combine with uncertain NCAR temperature observation.

# Should I Worry About Ice Going Down the Hill?

Standard Ensemble Filter:  
Fit a normal to the forecast  
ensemble.

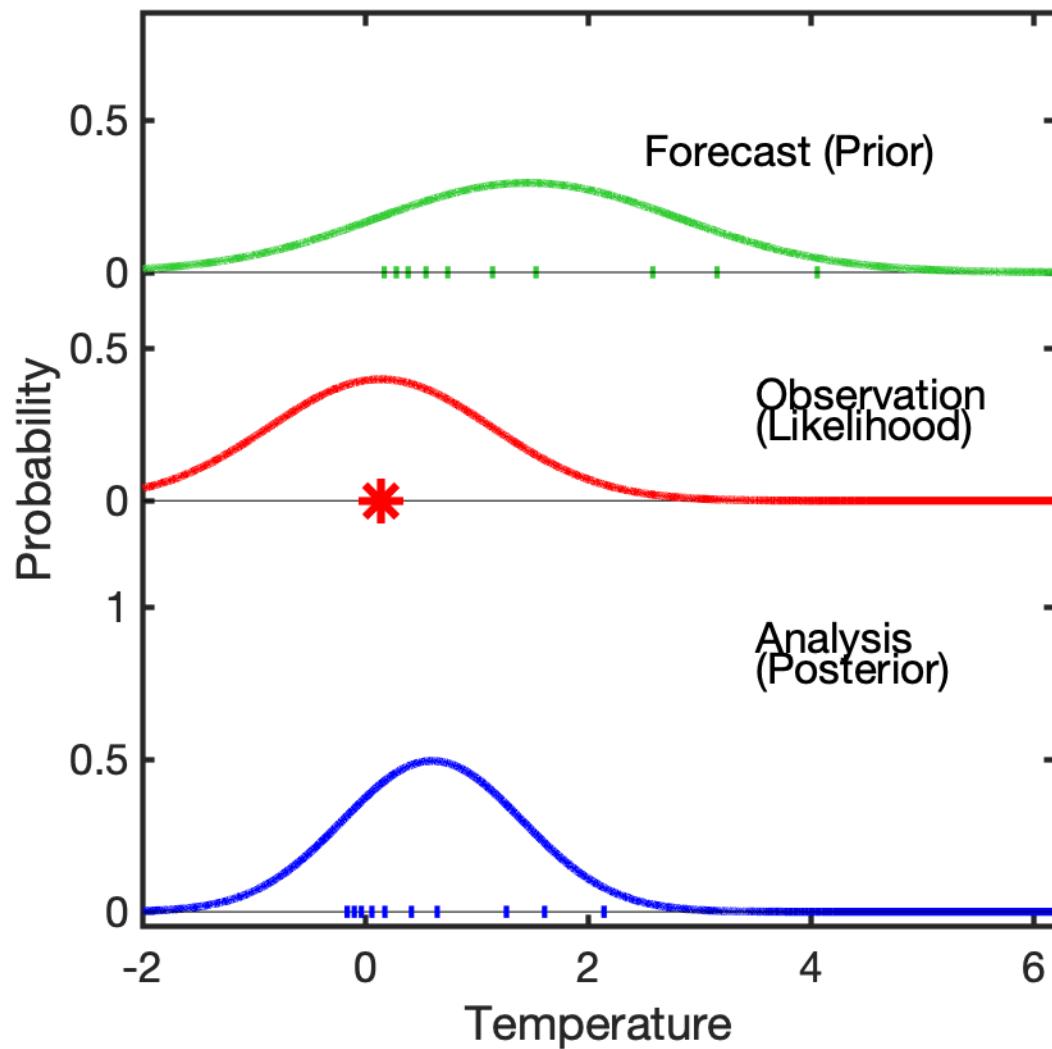

# Should I Worry About Ice Going Down the Hill?

Bayes product gives continuous normal posterior.

$$p(x, t_k | Y_{t_k}) = \frac{p(y_k | x) p(x, t_k | Y_{t_{k-1}})}{\int p(y_k | \xi) p(\xi, t_k | Y_{t_{k-1}}) d\xi}$$

# Should I Worry About Ice Going Down the Hill?

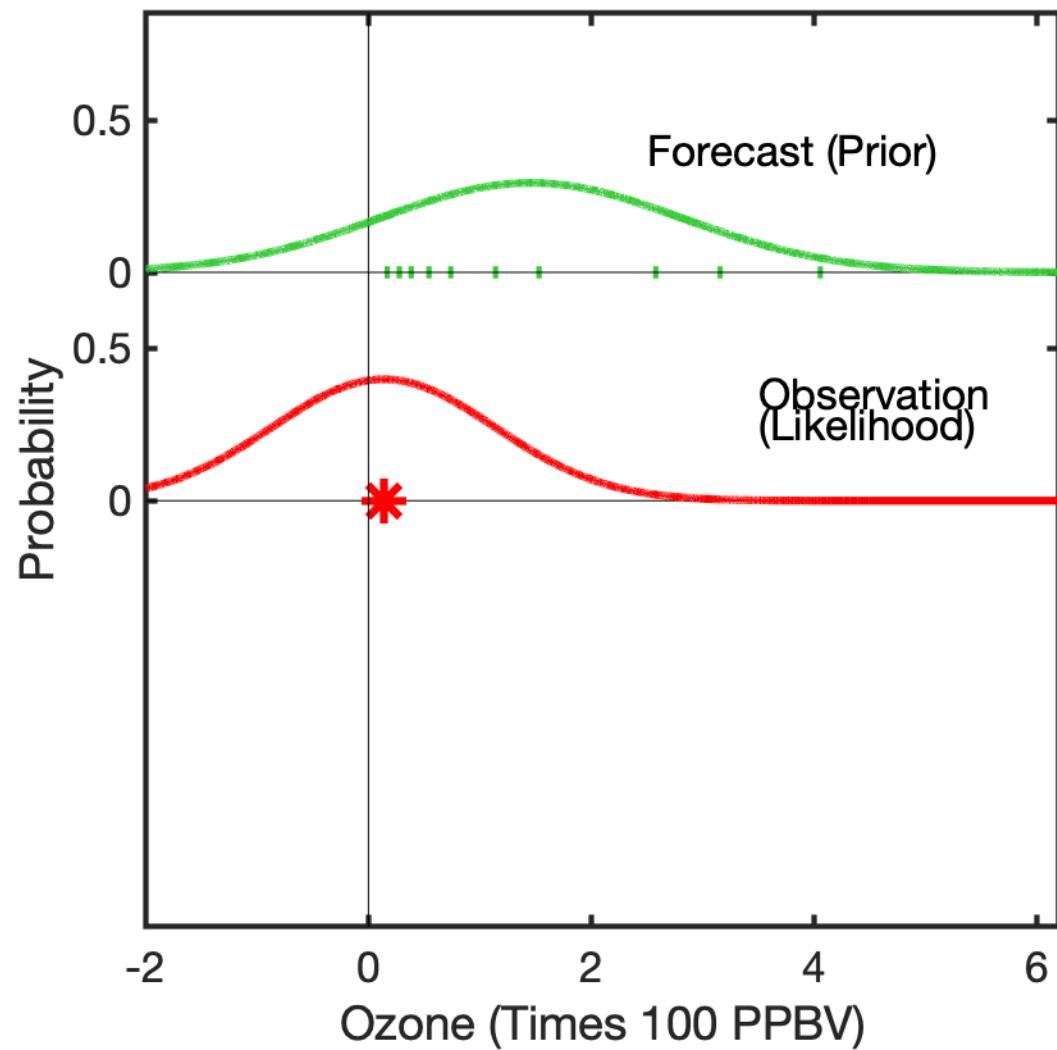

Get a posterior ensemble.

At one time, we only knew how to do this for normal distributions.

Normal may work okay for applications like NWP.

# Should I Worry About Air Quality Going Down the Hill?

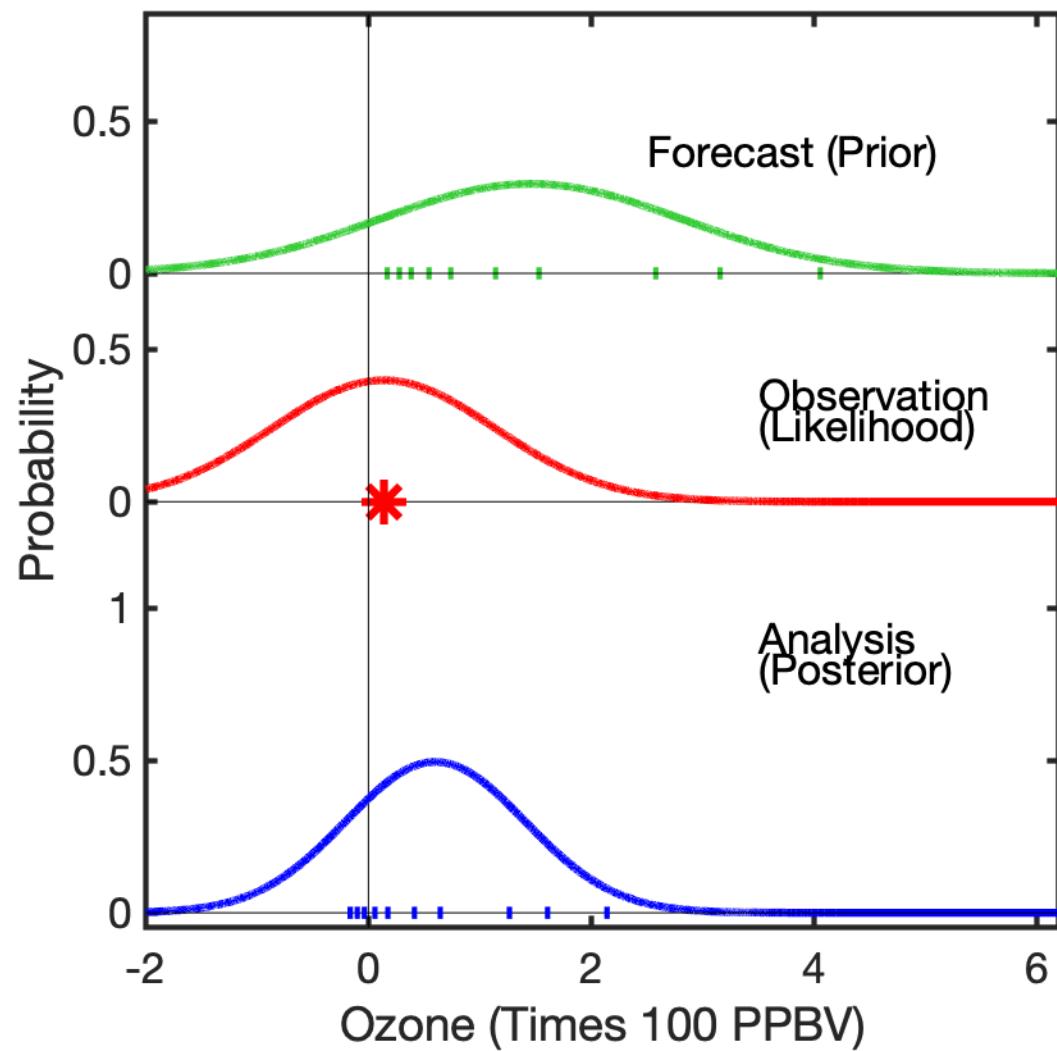

Forecast model knows ozone must be positive.

Fitting a normal leads to probability of negative.

# Should I Worry About Air Quality Going Down the Hill?

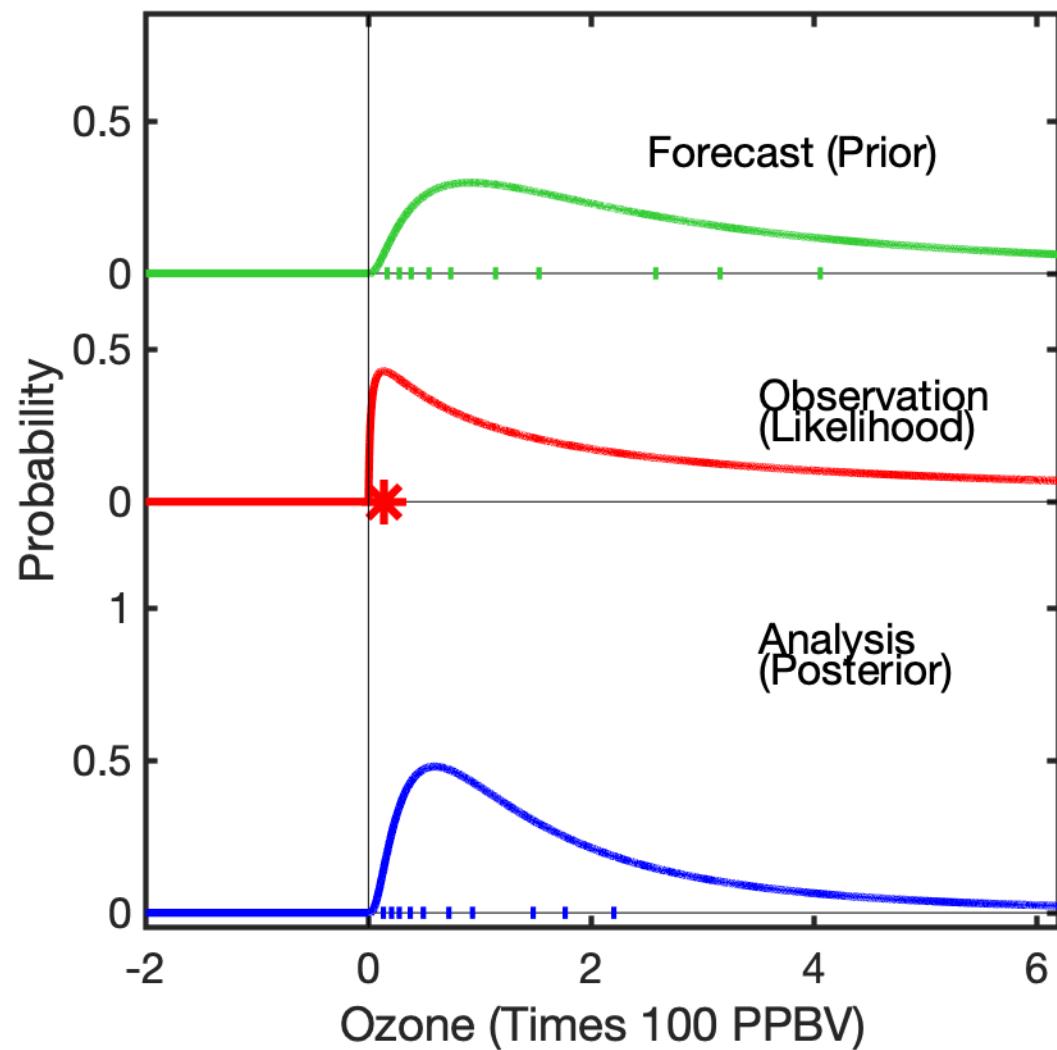

Doing the DA can lead to negative ensemble members.

What does that mean? Not sure, but nothing good.

Putting these back into model to make new forecasts is a problem, too.

# Should I Worry About Air Quality Going Down the Hill?

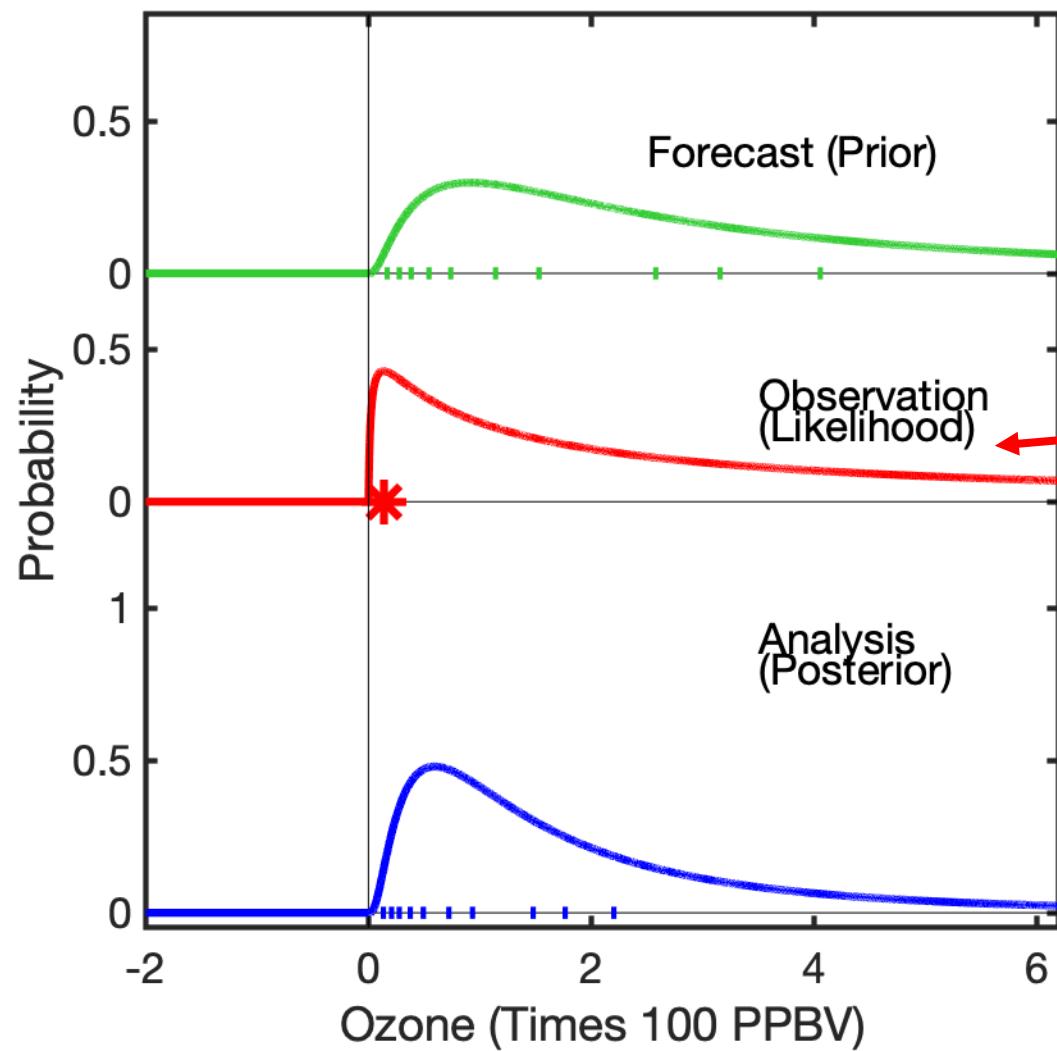

Now **can do any distribution** using quantile conserving ensemble algorithms.

Example: Gamma for bounded quantity like ozone.

Posterior ensemble no longer crazy.

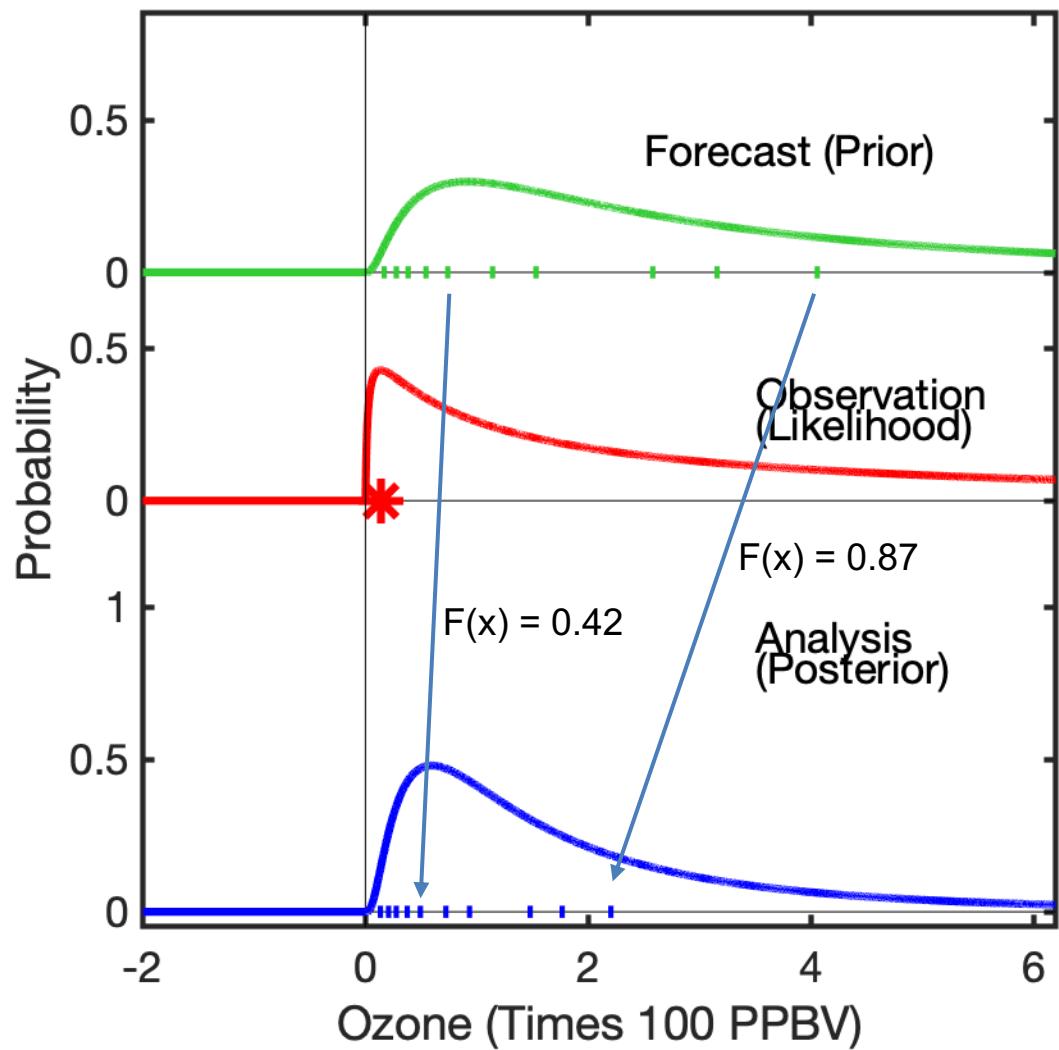

# Should I Worry About Air Quality Going Down the Hill?

Now **can do any distribution** using quantile conserving ensemble algorithms.

Can now use much more general information about observation error from instrument experts. Nice collaborations are possible.

# Quantile Conserving Ensemble Filter Framework

How to select ensembles  
for the analysis  
distribution?

Conserve quantiles from  
the prior ensemble.

$F$  is the cumulative  
distribution function (CDF)  
for the prior or analysis  
continuous distribution. It  
gives the quantile.

# Introduction: Quantile Conserving Ensemble Filter Framework

- Ensemble Kalman filters are effective but make implicit assumptions about normal distributions
- Present a generalization for ensemble ~~Kalman~~ filters that can use arbitrary **univariate** distributions

# Key (very simple) Innovation

- Getting continuous PDF from ensemble is often simple.
  - Sample mean, variance for many distributions.
- Getting ‘nice’ ensemble from continuous PDF has been harder.

A Solution: **Conserve quantiles of ensemble** to sample a modified PDF.

Posterior ensemble quantiles are the same as prior ensemble quantiles.

# Quantile Conserving Ensemble Filter Framework

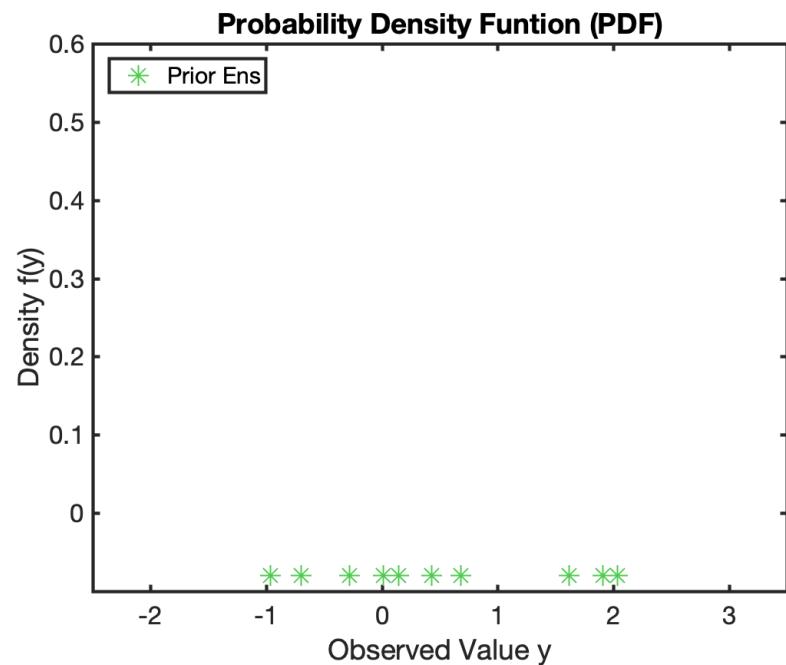

1. Pick any appropriate continuous PDF given an ensemble.
2. Get the corresponding CDF,  $F^p$ .
3. Compute quantiles of ensemble members,  $F^p(x_n^p)$ ,  $n = 1, \dots, N$ .
4. Modify the PDF (filter, inflate, localize, whatever).
5. Get the modified analysis CDF,  $F^a$ .
6. Updated ensemble conserves quantiles,  
$$x_n^a = (F^a)^{-1}[F^p(x_n^p)], n = 1, \dots, N.$$

Generalized inverse if  $F^a$  is not invertible

$$(F^a)^{-1}(y) = \min\{x : y \leq F^a(x)\}.$$

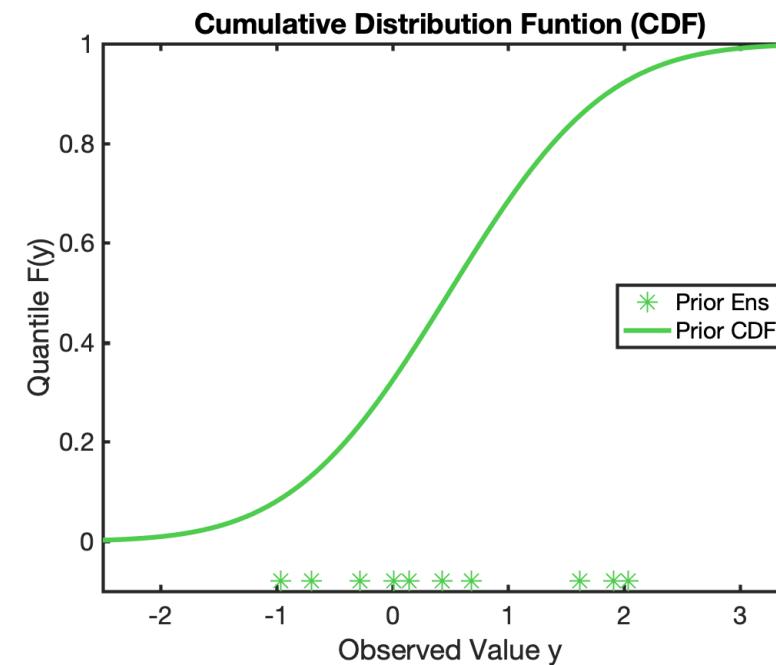

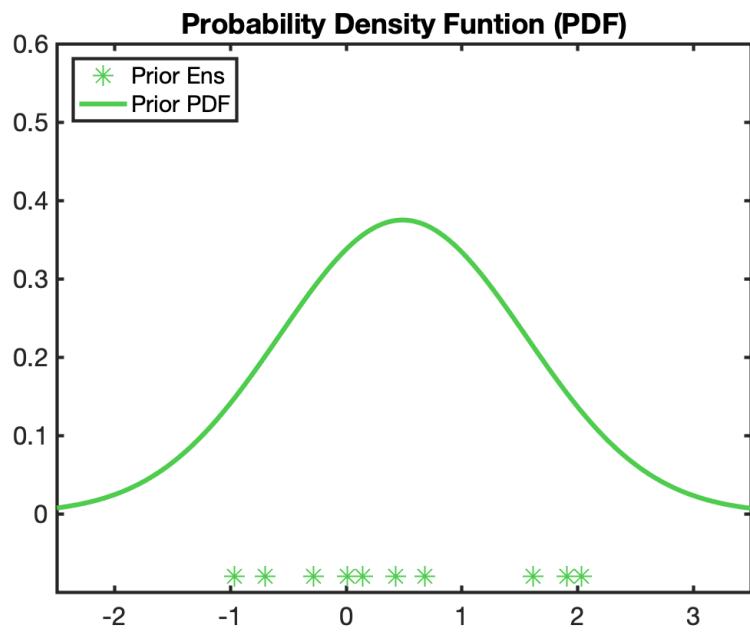

# Application 1: Bayesian filtering for an observed variable

Given a prior ensemble estimate of an observed quantity,  $y$ ,

# Application 1: Bayesian filtering for an observed variable

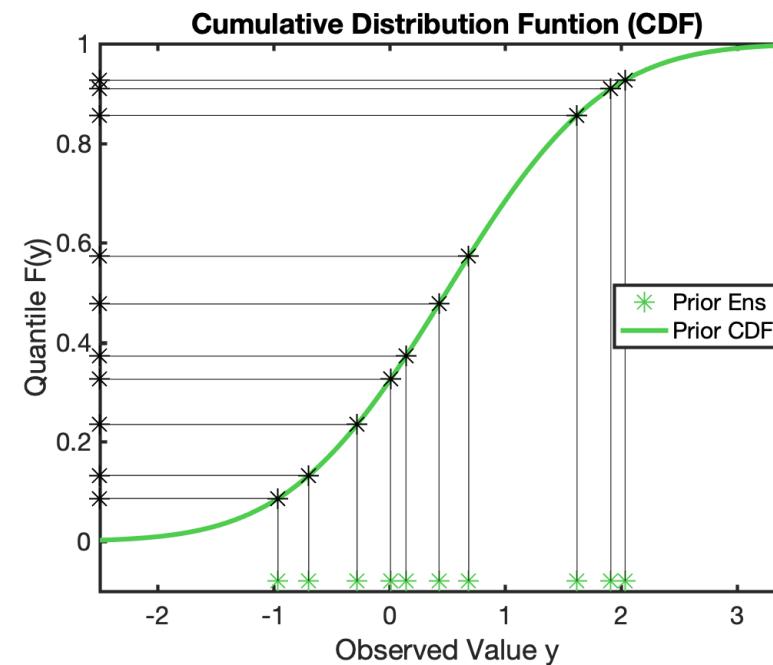

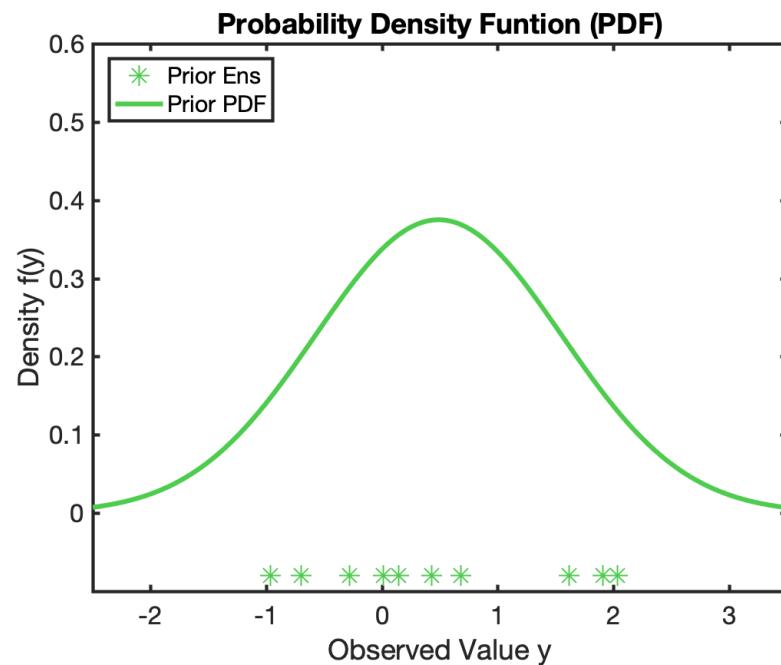

Fit a continuous PDF from an appropriate distribution family and find the corresponding CDF.

This example uses a normal PDF.

# Application 1: Bayesian filtering for an observed variable

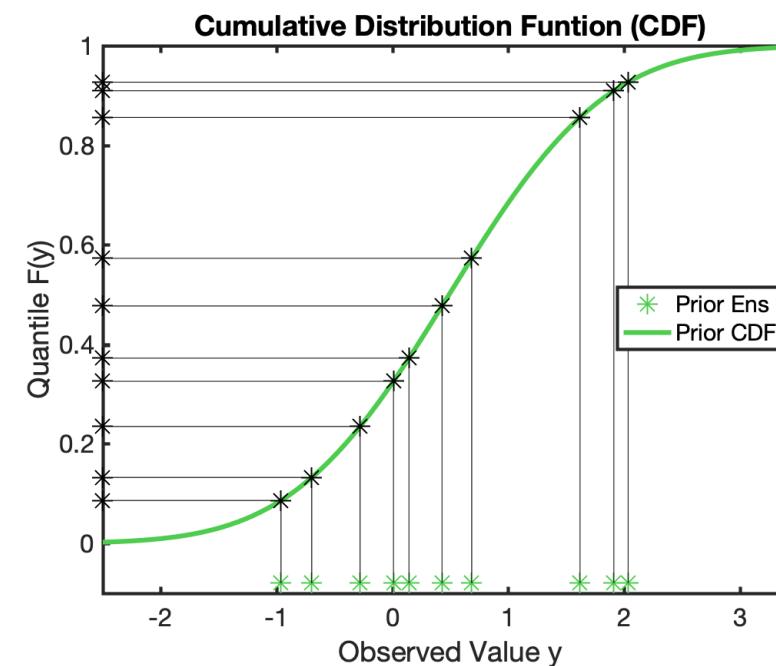

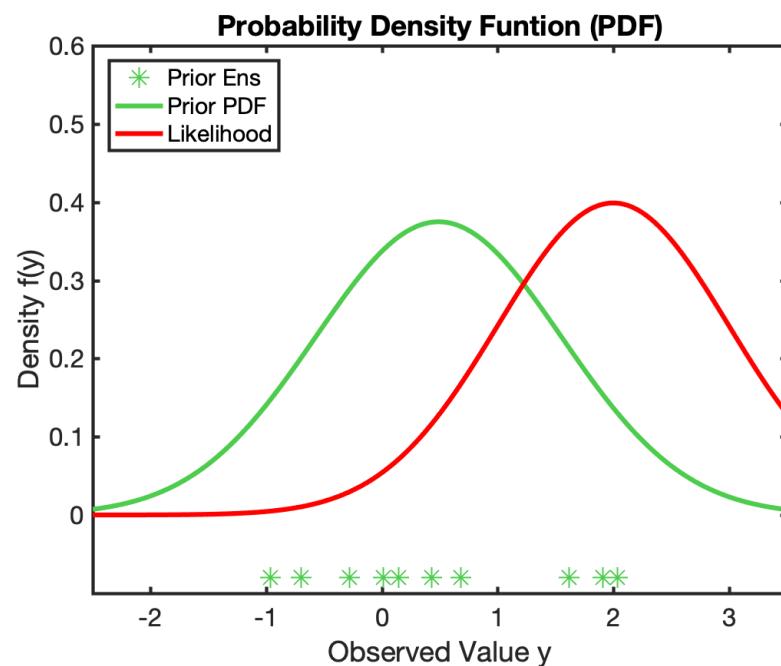

Compute the quantile of ensemble members;  
just the value of CDF evaluated for each member.

This example uses a normal PDF.

# Application 1: Bayesian filtering for an observed variable

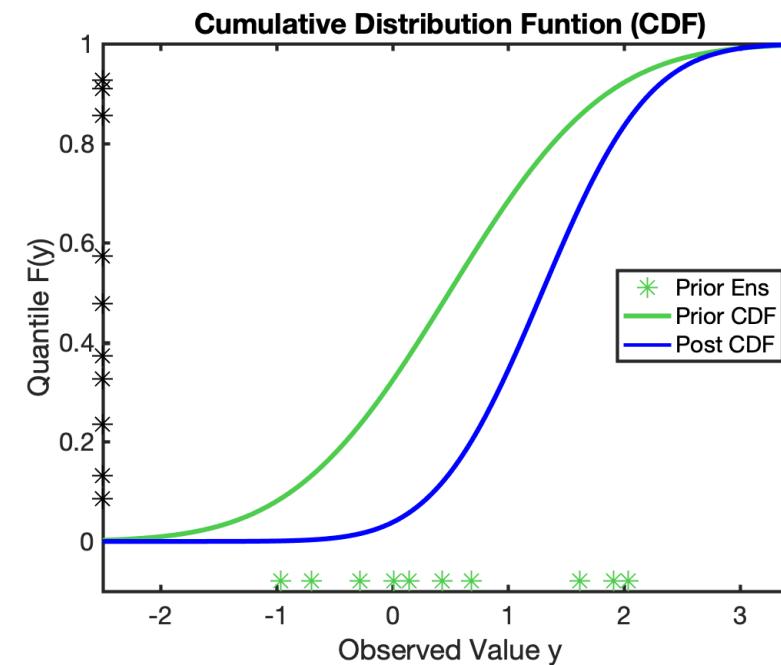

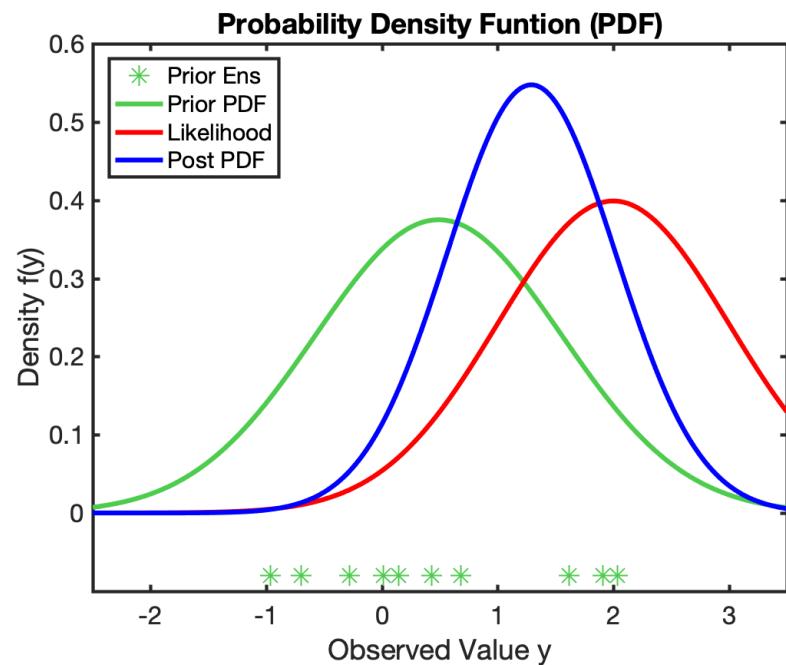

Continuous likelihood for this observation.

This example uses a normal PDF.

# Application 1: Bayesian filtering for an observed variable

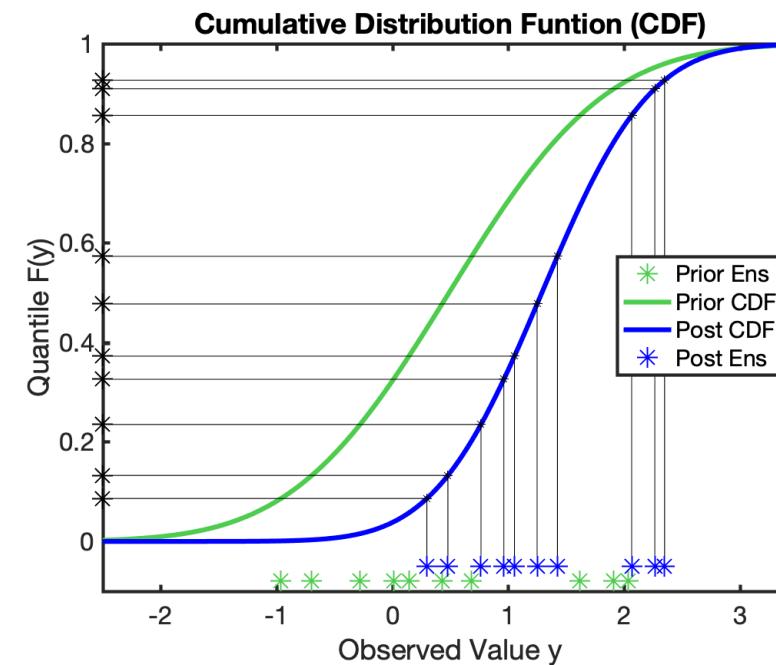

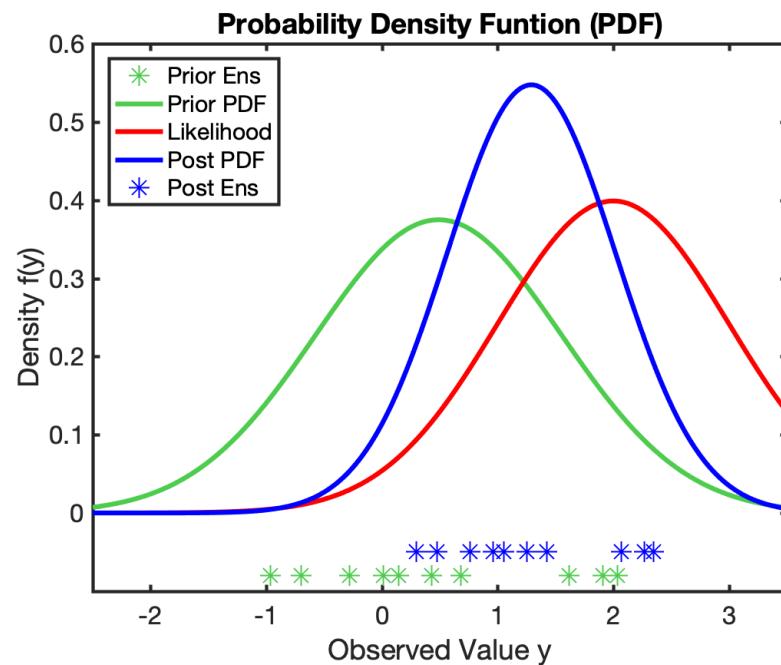

Bayes tells us that the continuous posterior PDF is the product of the continuous likelihood and prior.

Normal times normal is normal.

# Application 1: Bayesian filtering for an observed variable

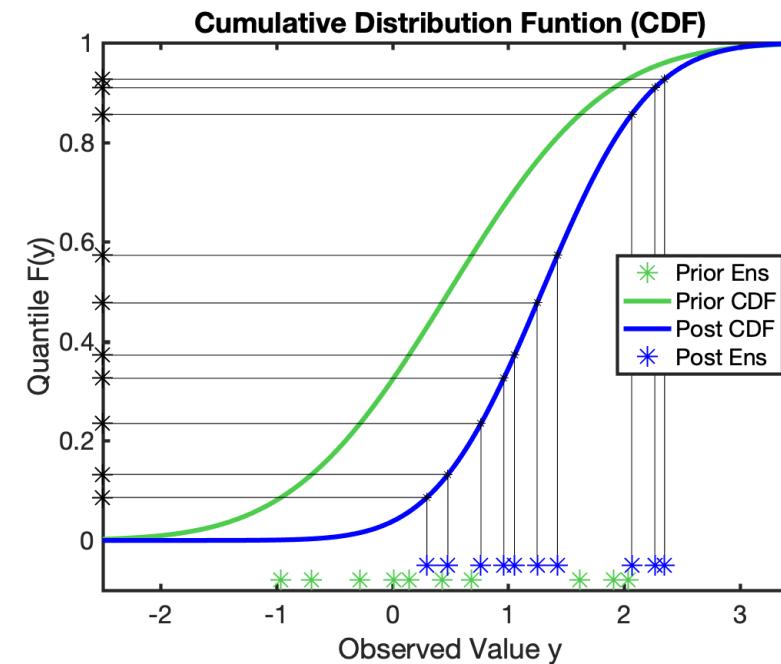

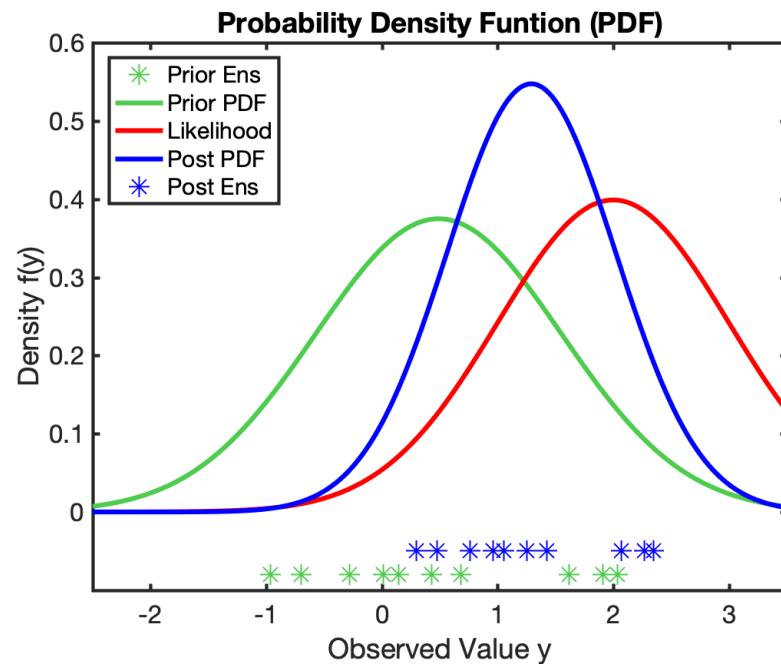

Posterior ensemble members have same quantiles as prior.  
This is quantile function, inverse of posterior CDF.

This example uses a normal PDF

# Application 1: Bayesian filtering for an observed variable

For normal prior and likelihood, this is identical to existing deterministic Ensemble Adjustment Kalman Filter (EAKF) described in section 1.

# Useful families for continuous priors and likelihoods

Different families of distributions for continuous priors and likelihoods can lead to analytic continuous posterior.

This is similar to the notion of conjugate priors for estimating parameters of distributions.

A list of prior / likelihood pairs that may be useful for scientific application follows.

# Useful families for continuous priors and likelihoods

# What if I Don't Know the Right Distribution?

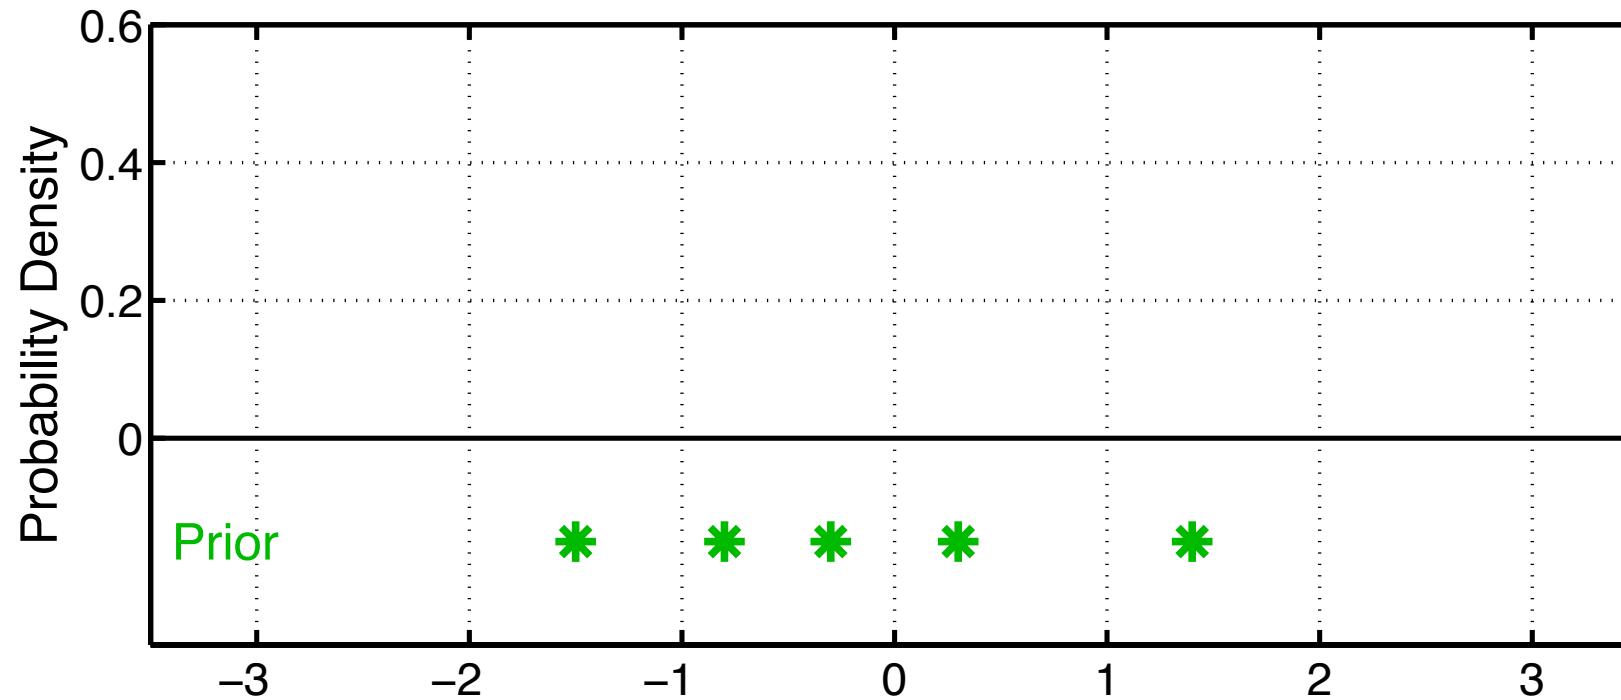

The Bounded Normal Rank Histogram Distribution works well for almost all cases.

Non-parametric. It builds a distribution from the ensemble.

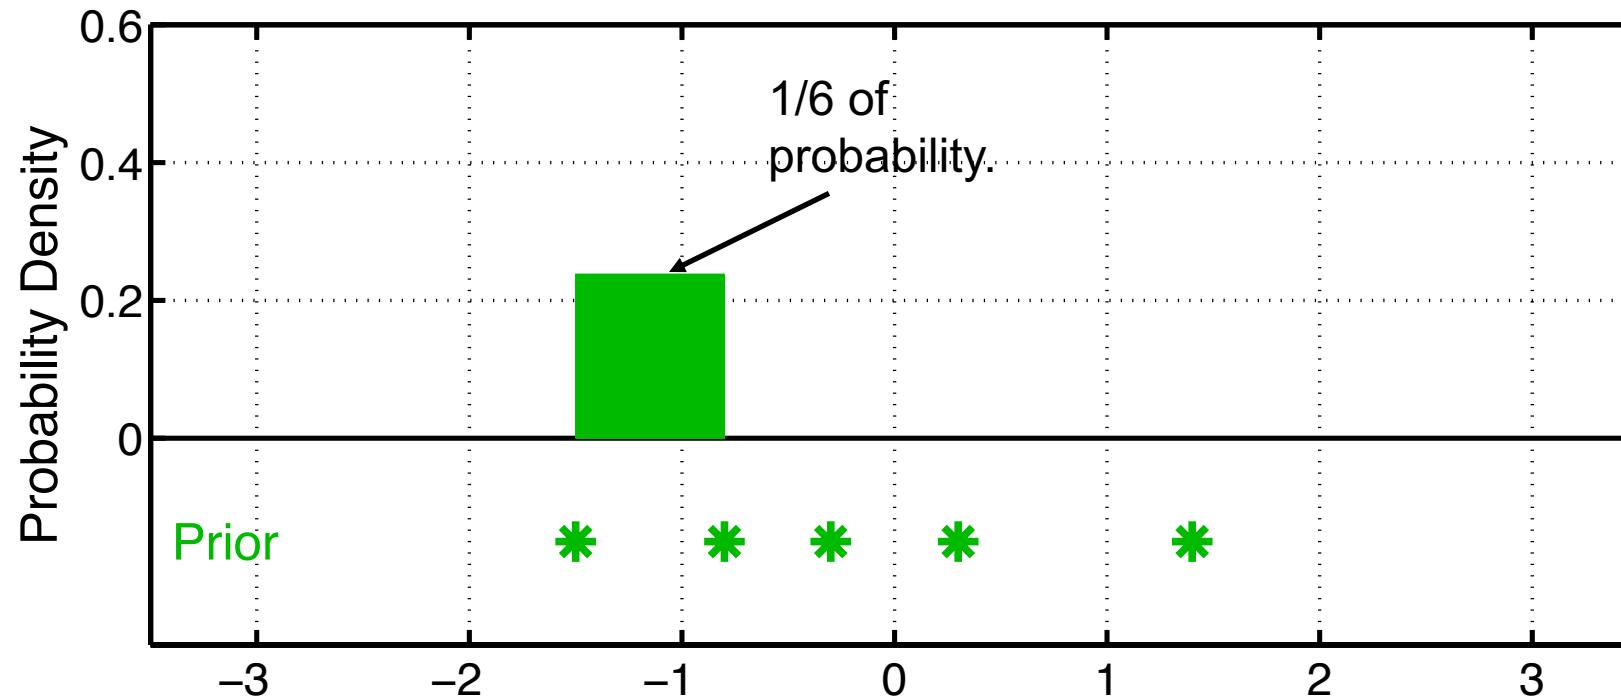

All examples here use this distribution.

# Bounded Normal Rank Histogram Continuous Prior

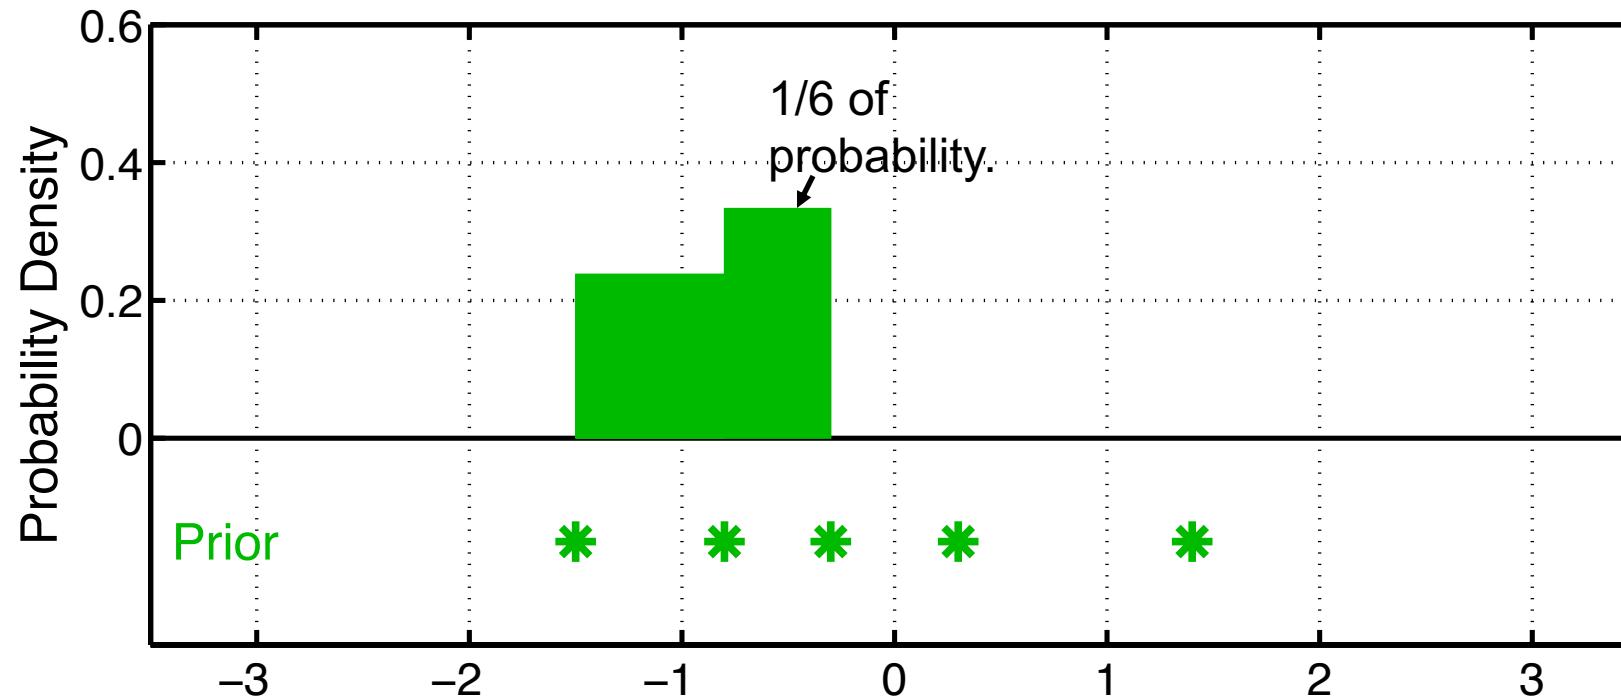

Have a prior ensemble for a state variable (like wind).

# Bounded Normal Rank Histogram Continuous Prior

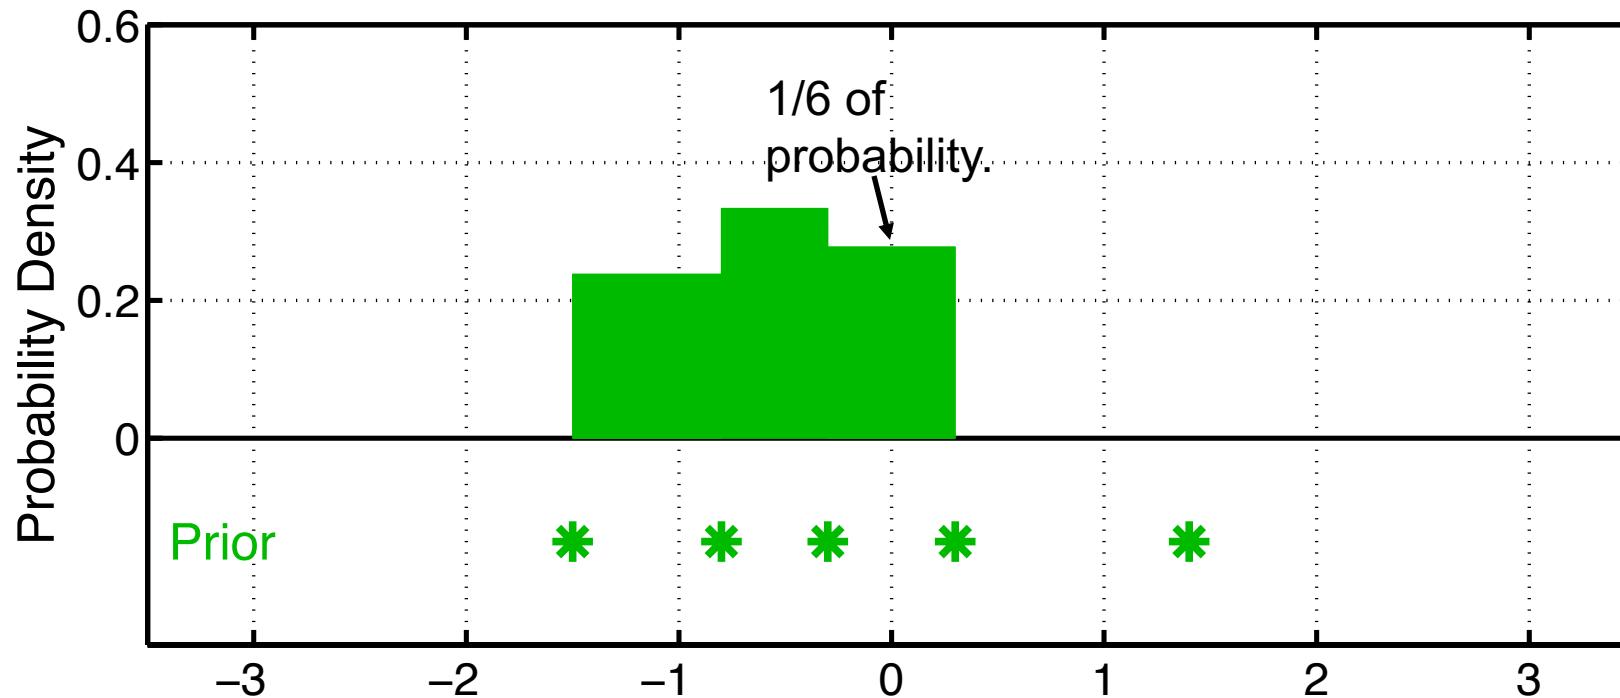

- Place  $(\text{ens\_size} + 1)^{-1}$  mass between adjacent ensemble members.
- Reminiscent of rank histogram evaluation method.

# Bounded Normal Rank Histogram Continuous Prior

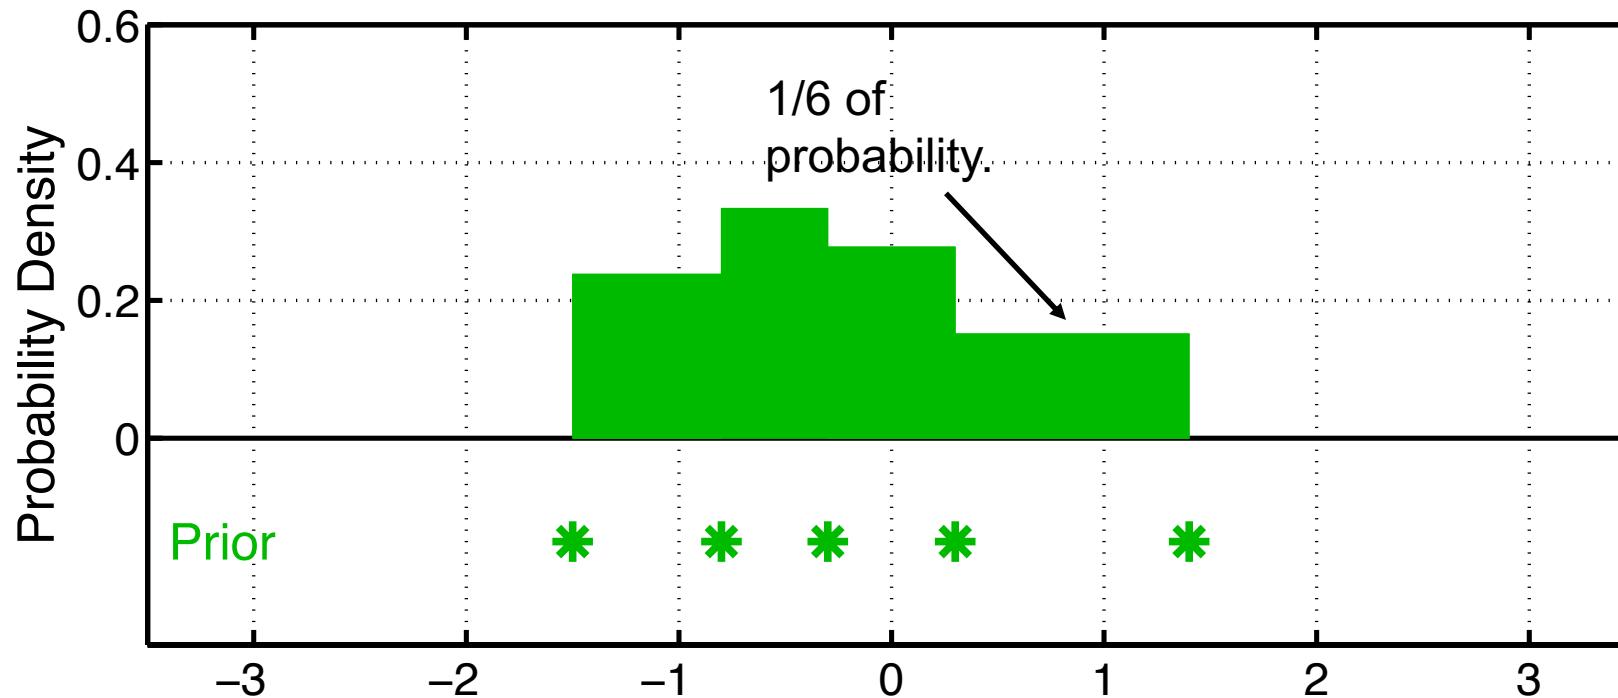

- Place  $(\text{ens\_size} + 1)^{-1}$  mass between adjacent ensemble members.
- Reminiscent of rank histogram evaluation method.

# Bounded Normal Rank Histogram Continuous Prior

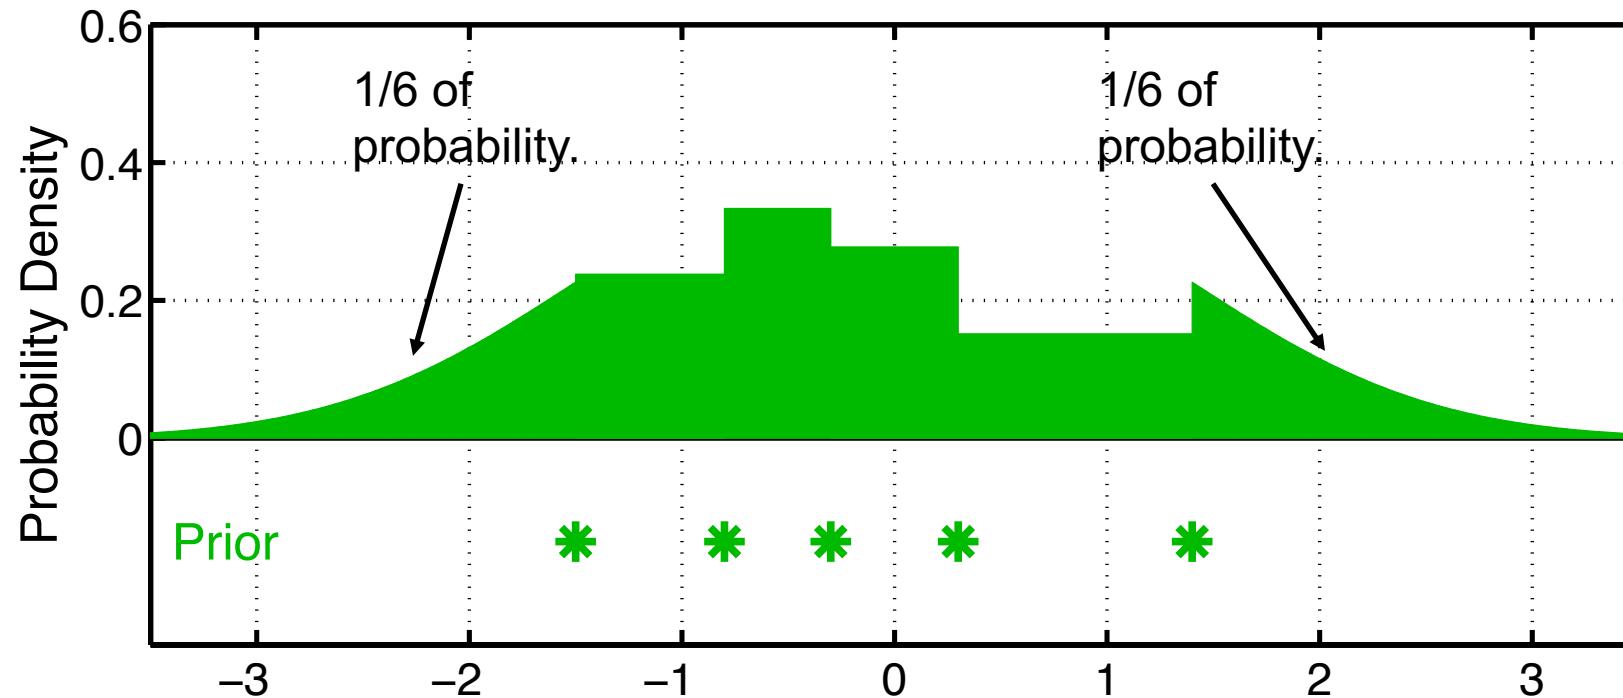

- Place  $(\text{ens\_size} + 1)^{-1}$  mass between adjacent ensemble members.
- Reminiscent of rank histogram evaluation method.

# Bounded Normal Rank Histogram Continuous Prior

- Place  $(\text{ens\_size} + 1)^{-1}$  mass between adjacent ensemble members.
- Reminiscent of rank histogram evaluation method.

# Bounded Normal Rank Histogram Continuous Prior

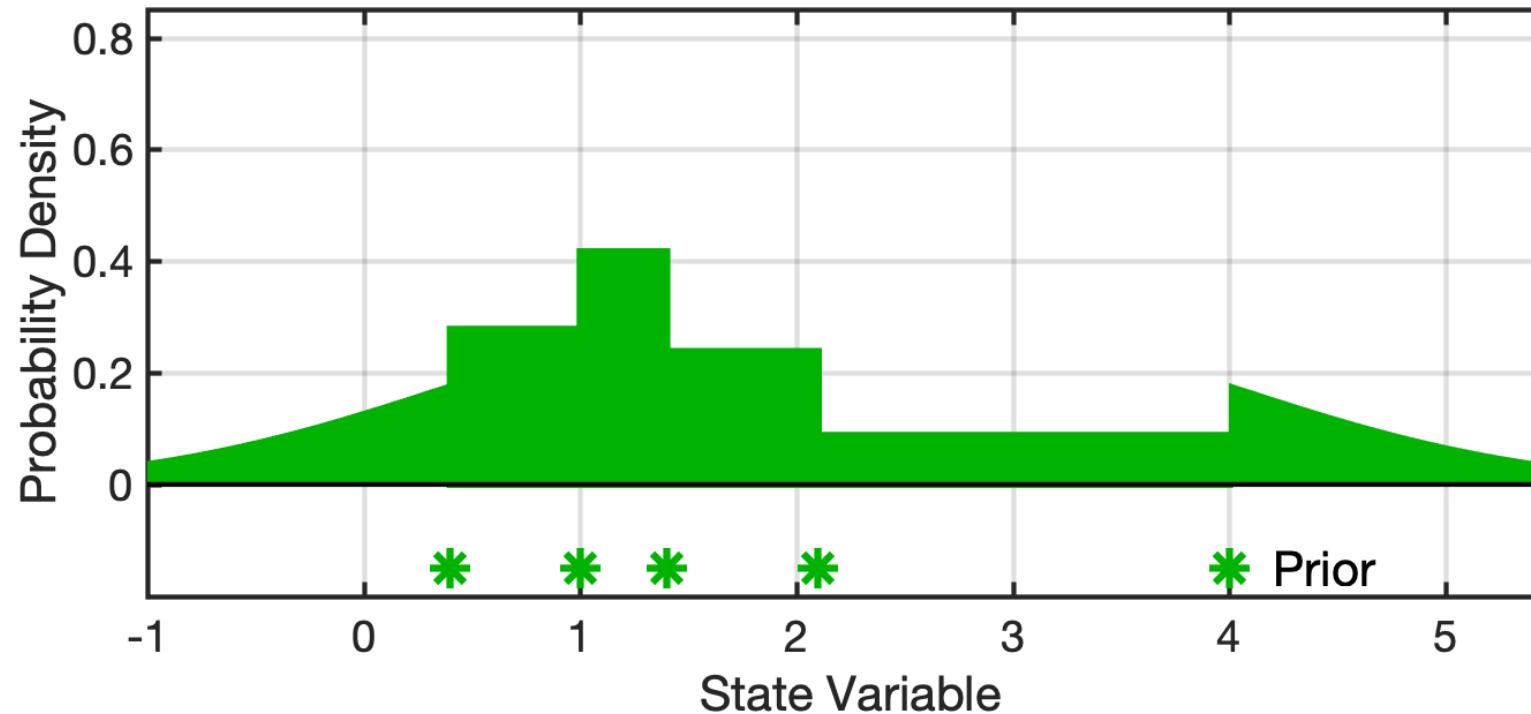

- Partial gaussian kernels on tails,  $N(tail\_mean, ens\_sd)$ .
- $tail\_mean$  selected so that  $(ens\_size + 1)^{-1}$  mass is in tail.

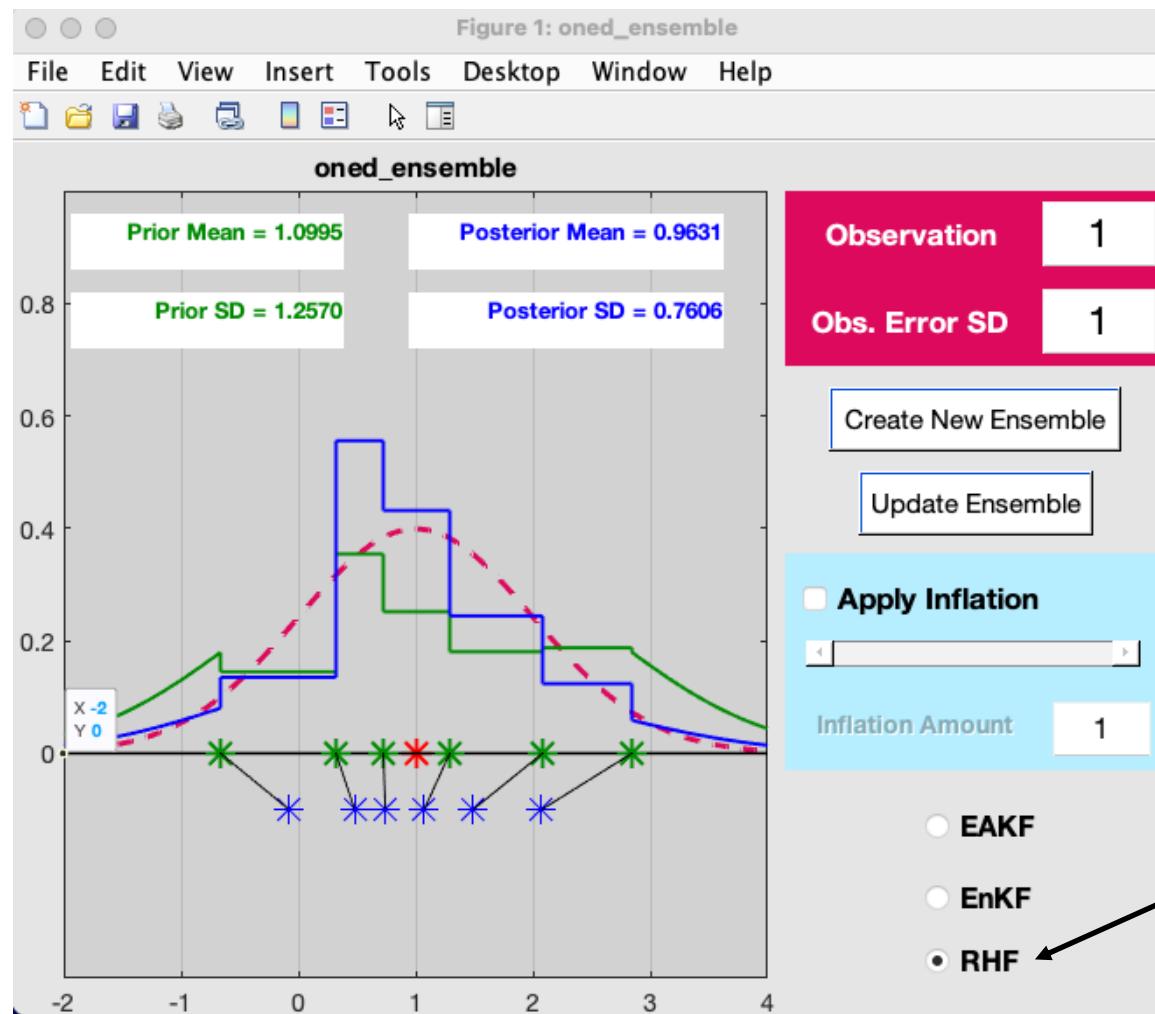

# Bounded Normal Rank Histogram Continuous Prior

Unbounded has normal tails.

Quantiles are exactly  $U(0, 1)$  by construction.

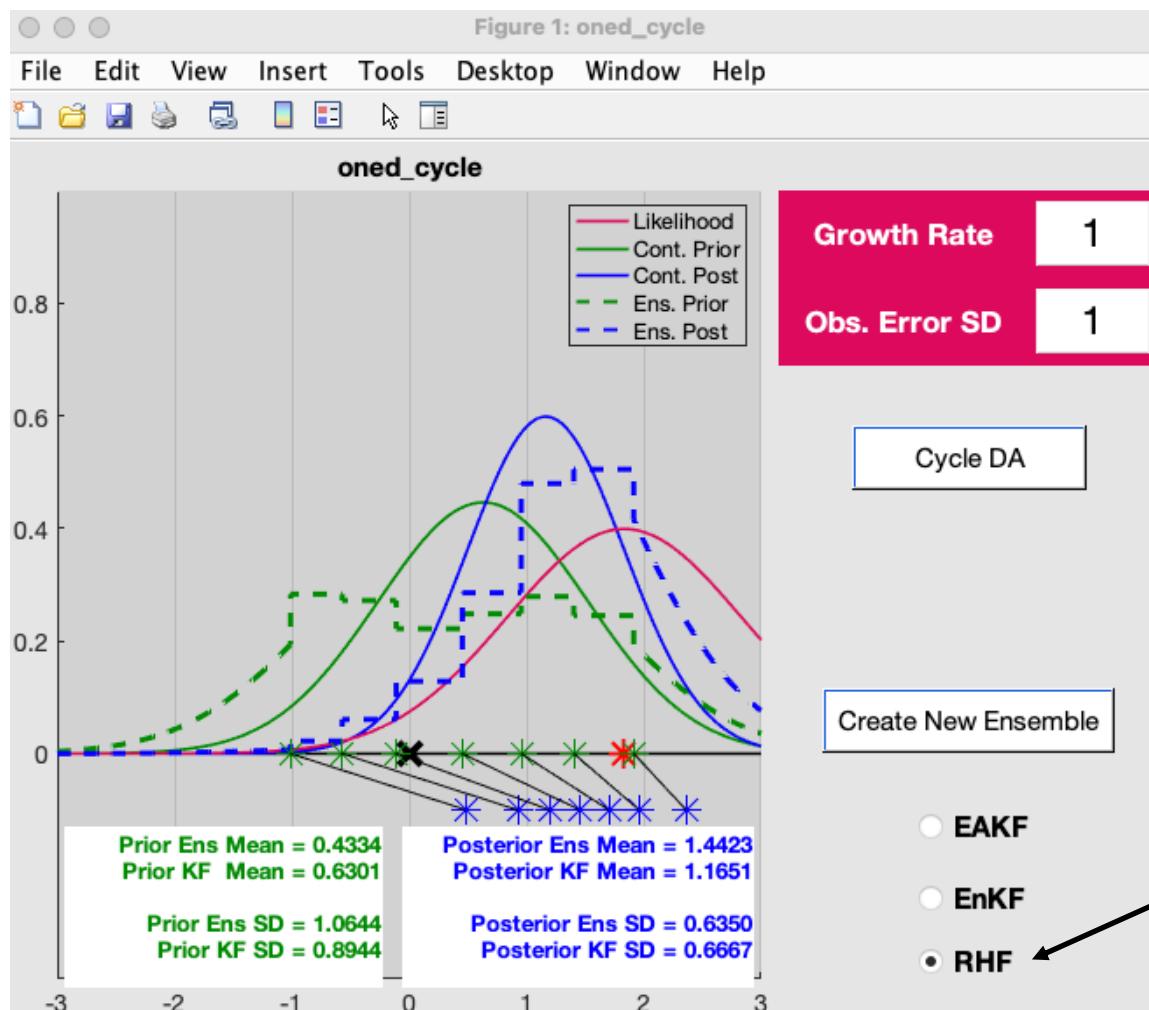

# Matlab Hands-on: oned\_ensemble

Select RHF to explore what priors and posteriors look like.

# Matlab Hands-on: oned\_cycle

Select RHF to explore what priors and posteriors look like.

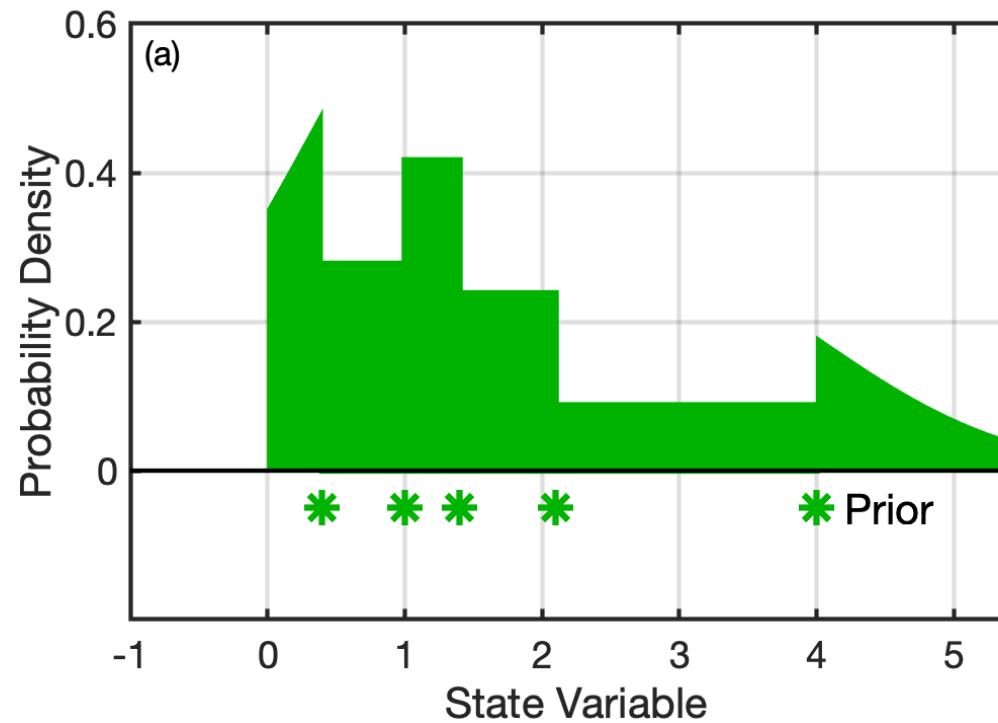

# Matlab Hands-on: More RHF example

The RHF can also be explored in:

oned\_model  
oned\_model\_inf  
twod\_ensemble  
run\_lorenz\_63  
run\_lorenz\_96  
run\_lorenz\_96\_inf

# Bounded Normal Rank Histogram Continuous Prior

Bounded has truncated tail, that is part of a normal.  
Quantiles are exactly  $U(0, 1)$  by construction.

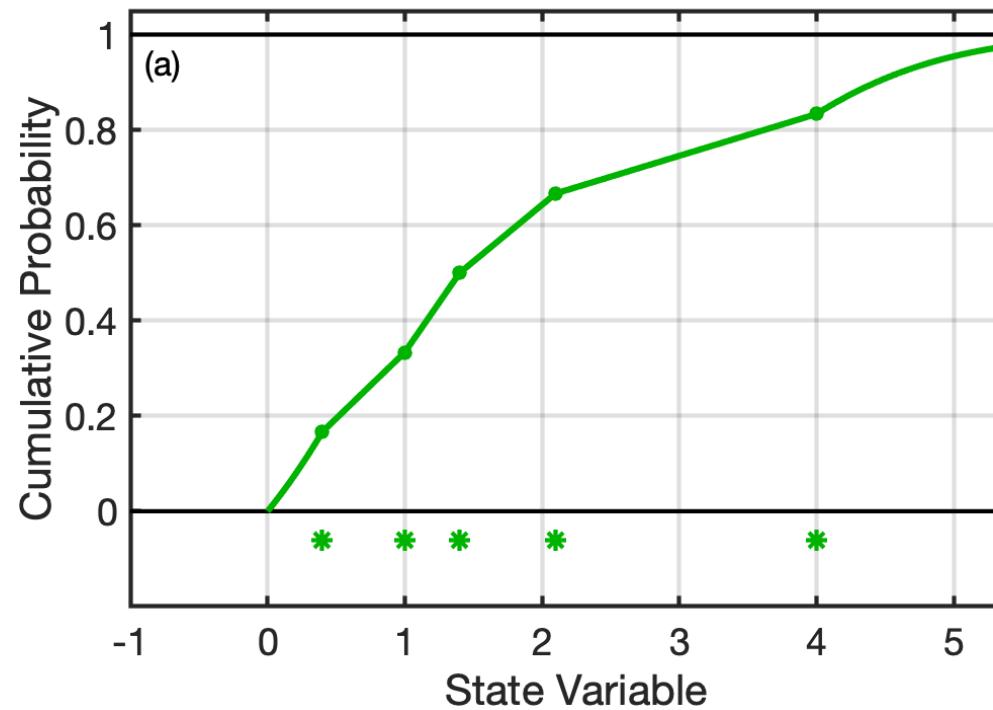

# Bounded Normal Rank Histogram Continuous Prior

Bounded has truncated tail, that is part of a normal.

Quantiles are exactly  $U(0, 1)$  by construction.

This is the corresponding CDF, doesn't look so weird.

# Mixed Distributions: A Challenge for Tracers and Sources

Mixed Distributions: Have both discrete and continuous probability distribution parts.

Precipitation forecast is an example:

Discrete probability of zero rain (50%),  
Continuous distribution for all non-zero amounts,  
(zero probability of exactly any given amount).

Important for some tracers.

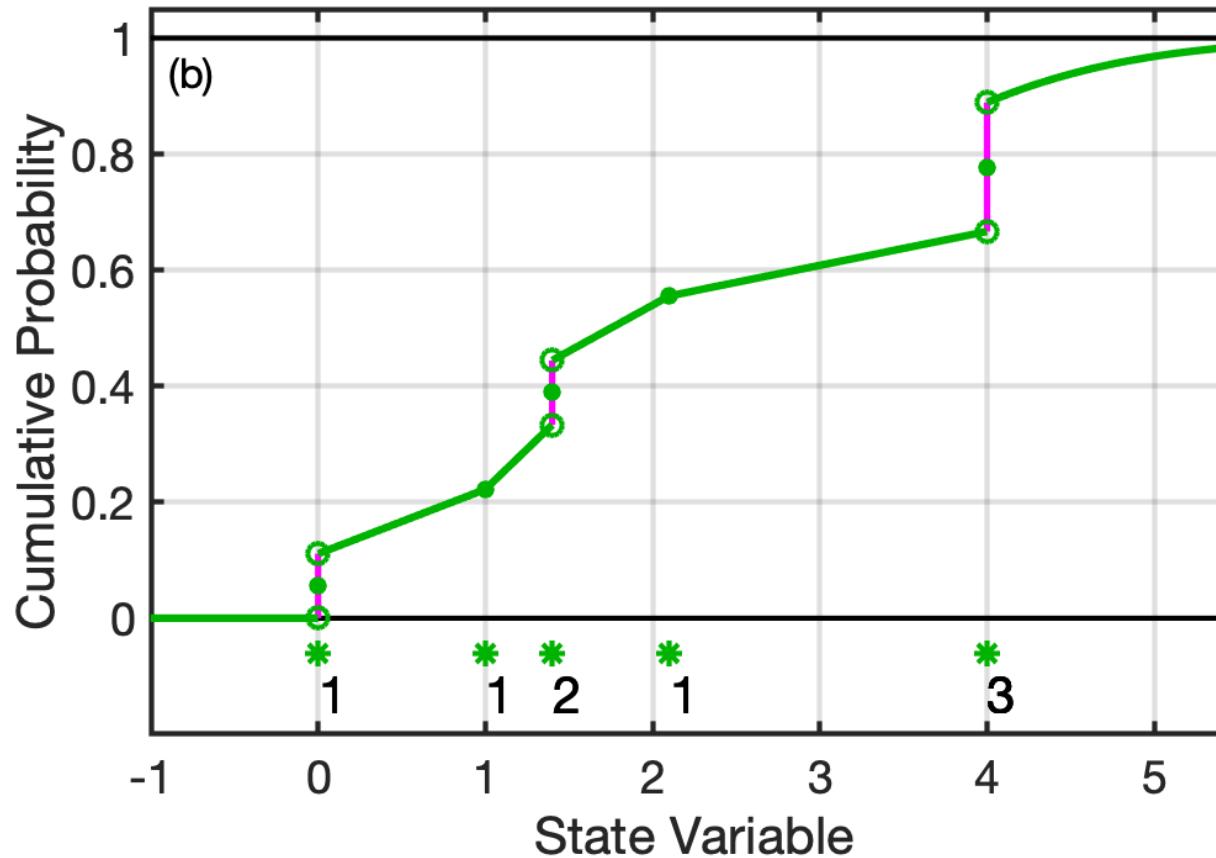

Important for many sources (anthropogenic sources, wildfires, ...).

(Anderson et al., 2024, MWR 152, 2111-2127)

# Mixed Distributions: A Challenge for Tracers and Sources

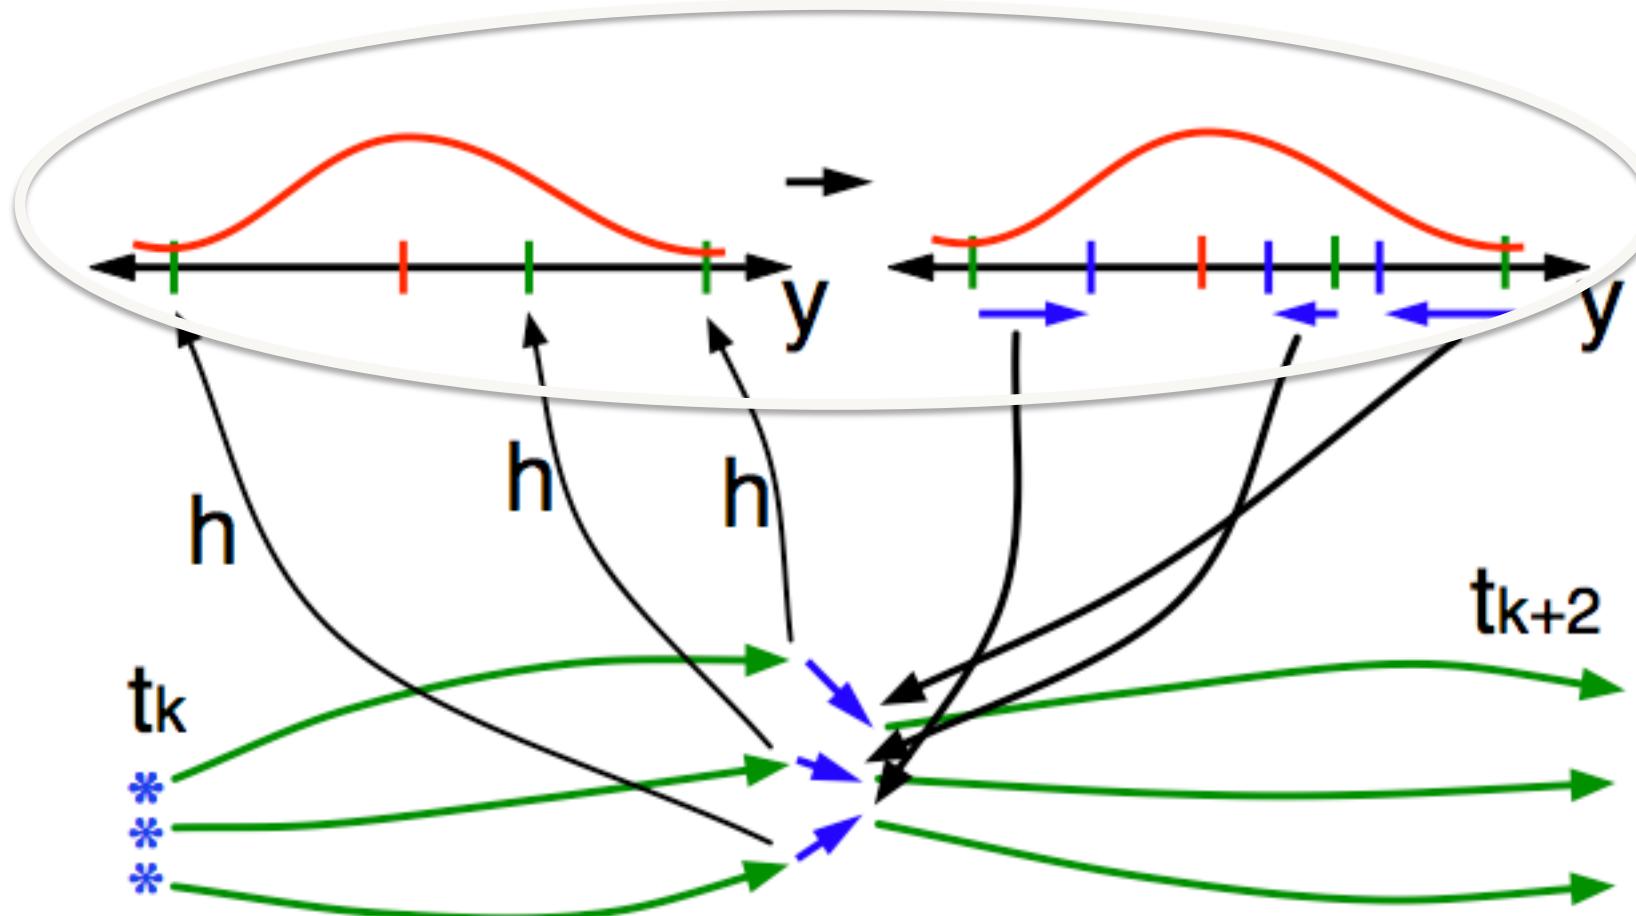

Need to be able to handle duplicate ensemble members.

$$\text{Want } x = F^{-1}(F(x)).$$

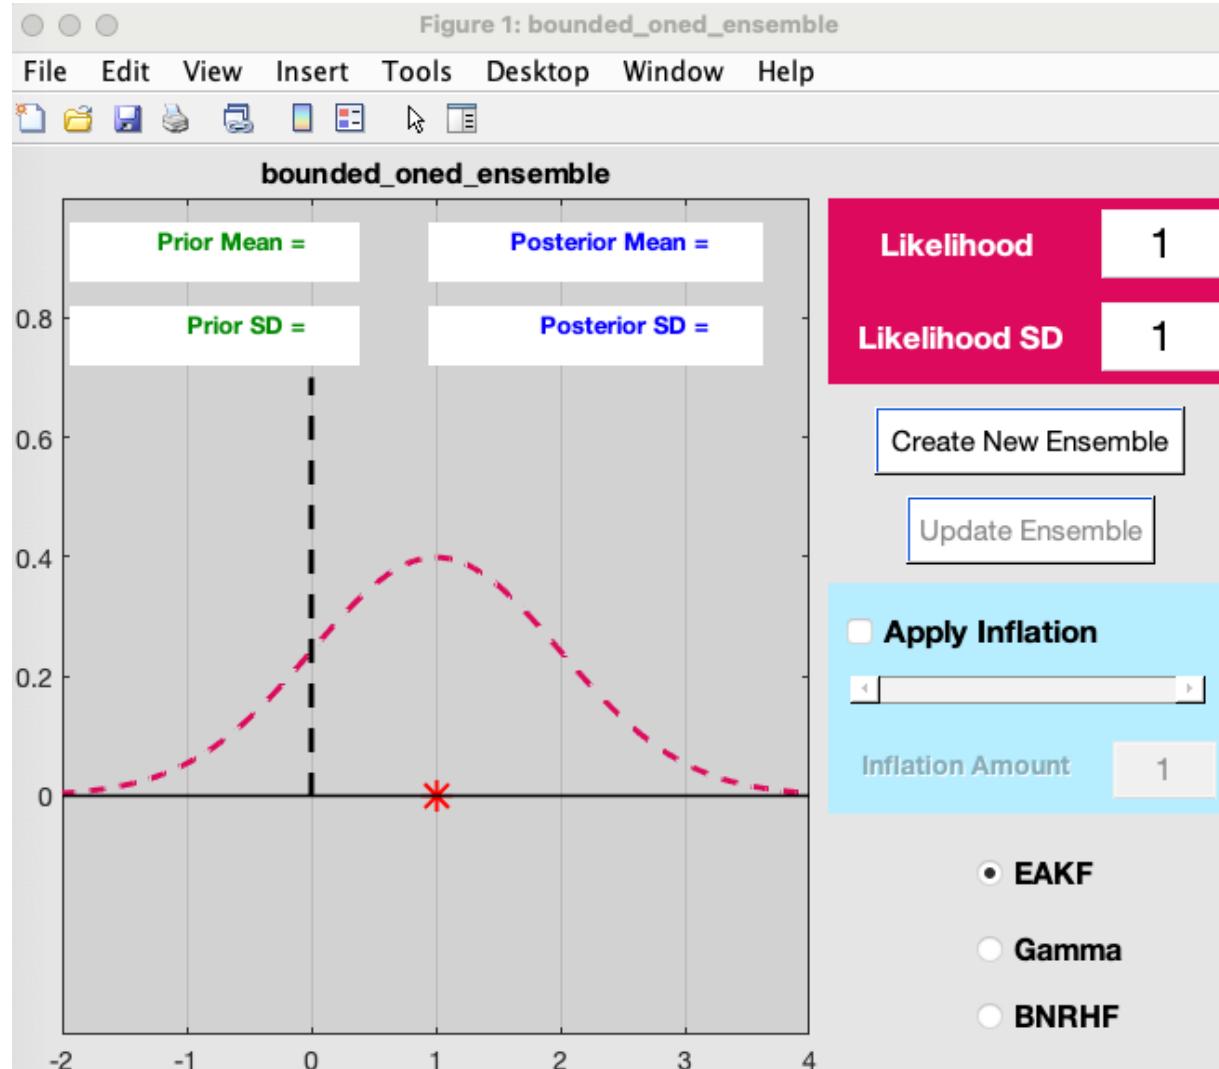

# Quantile Conserving Ensemble Filters in Observation Space

DART now provides nearly general solutions for this step:  
(Anderson, 2022, MWR150, 1061-1074).

# Matlab Hands-on: bounded\_oned\_ensemble

Controls are similar to oned\_ensemble but the quantity is non-negative.

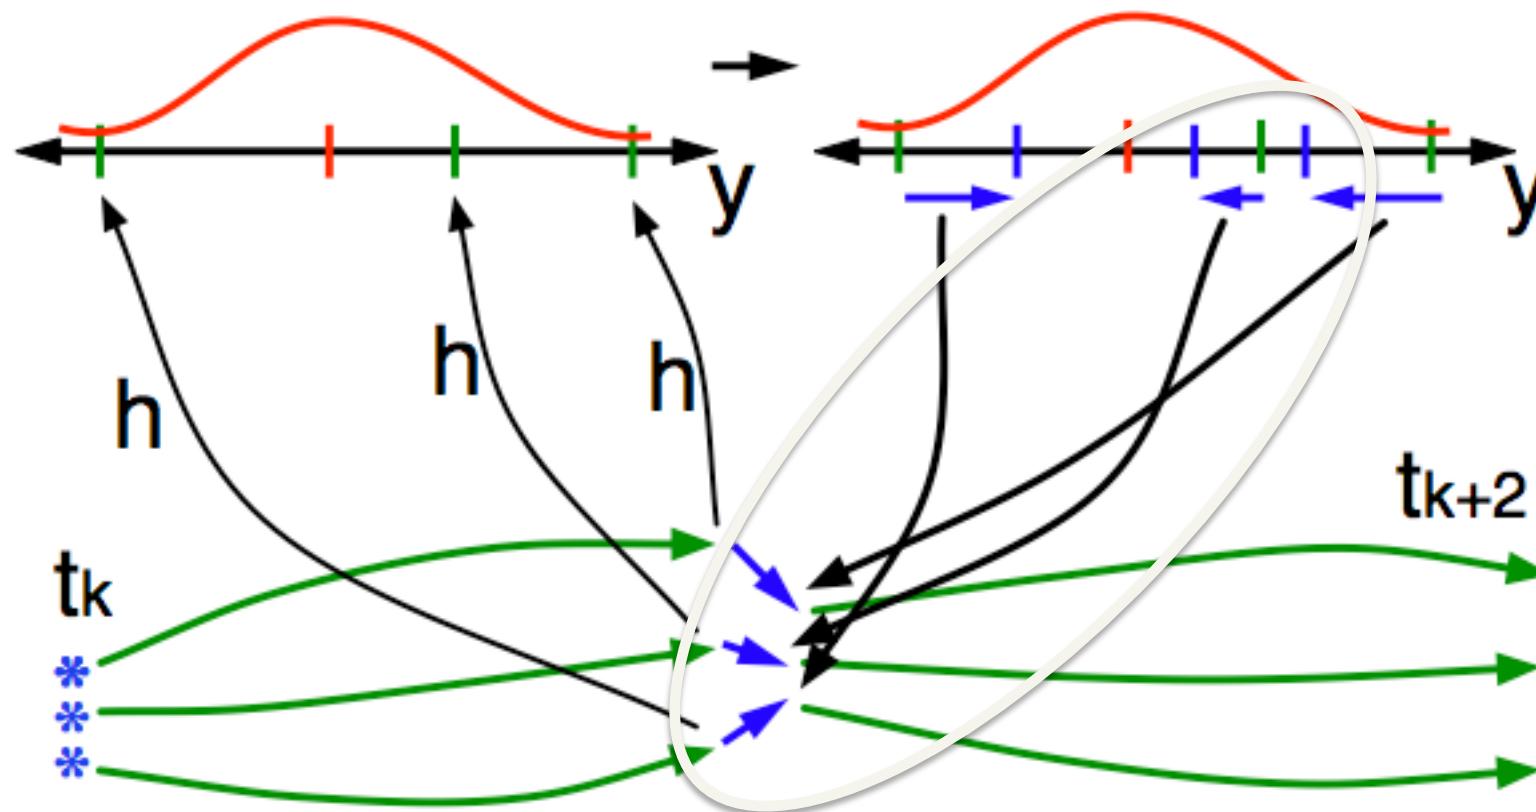

The EAKF (normal prior) doesn't know about this bound. Try to generate negative posterior ensemble members.

The Gamma distribution does know about the bounds.

The bounded normal rank histogram prior also knows about the bounds.

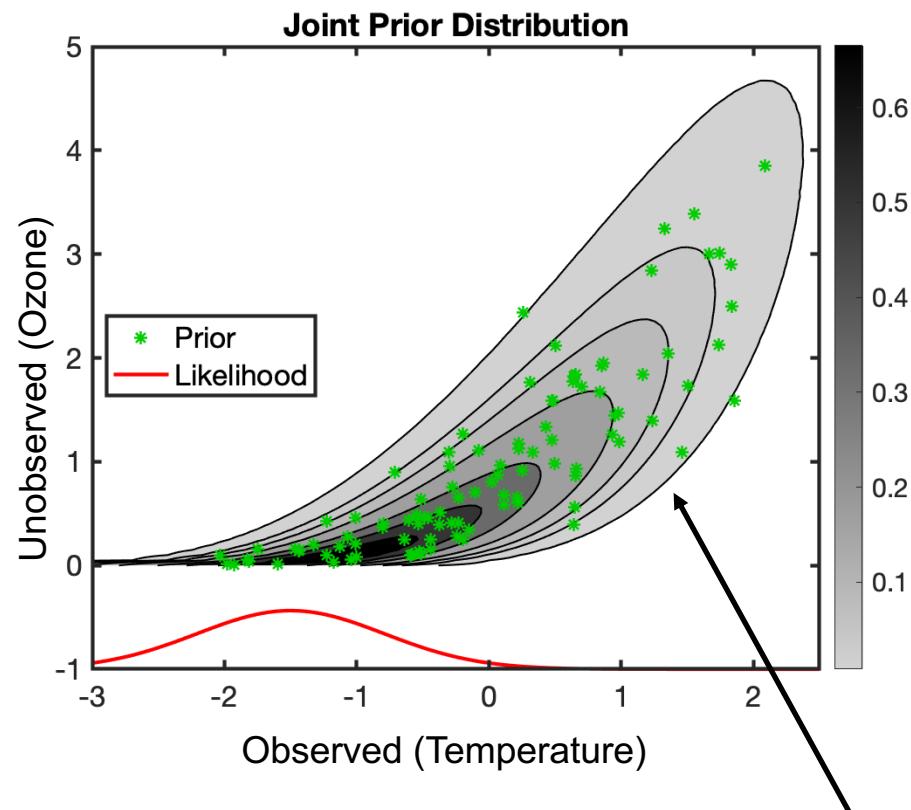

# Linear Regression can Wreck Things

Linear regression can destroy benefits of new observation method.

# Standard EAKF: Challenged by Non-Gaussian and Nonlinear Relations

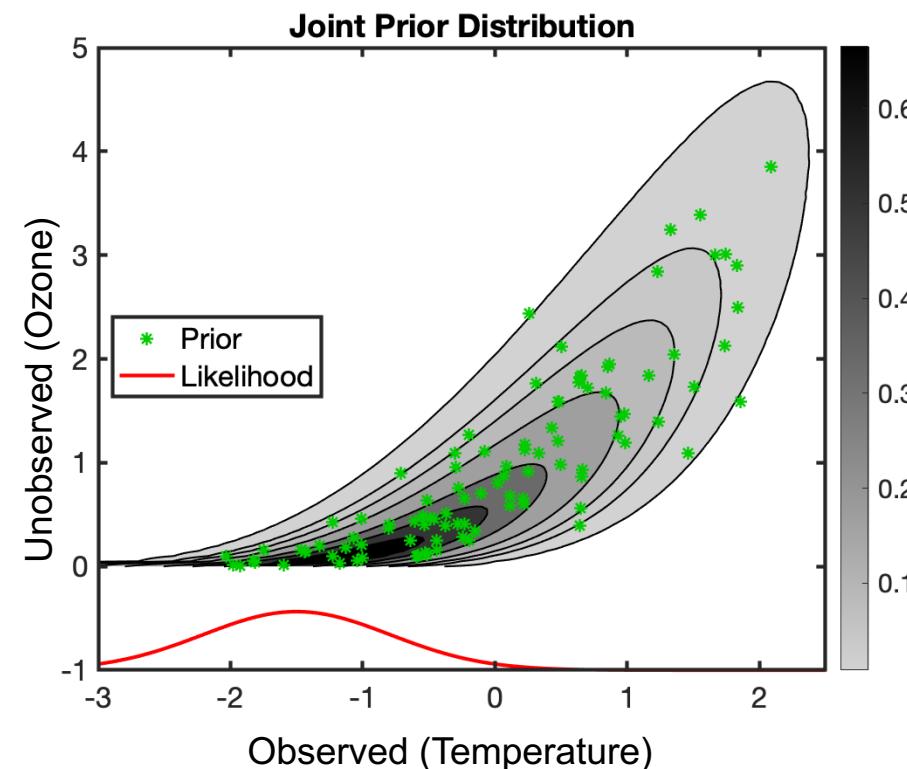

Prior for normal-gamma distribution  
with 100 member ensemble.

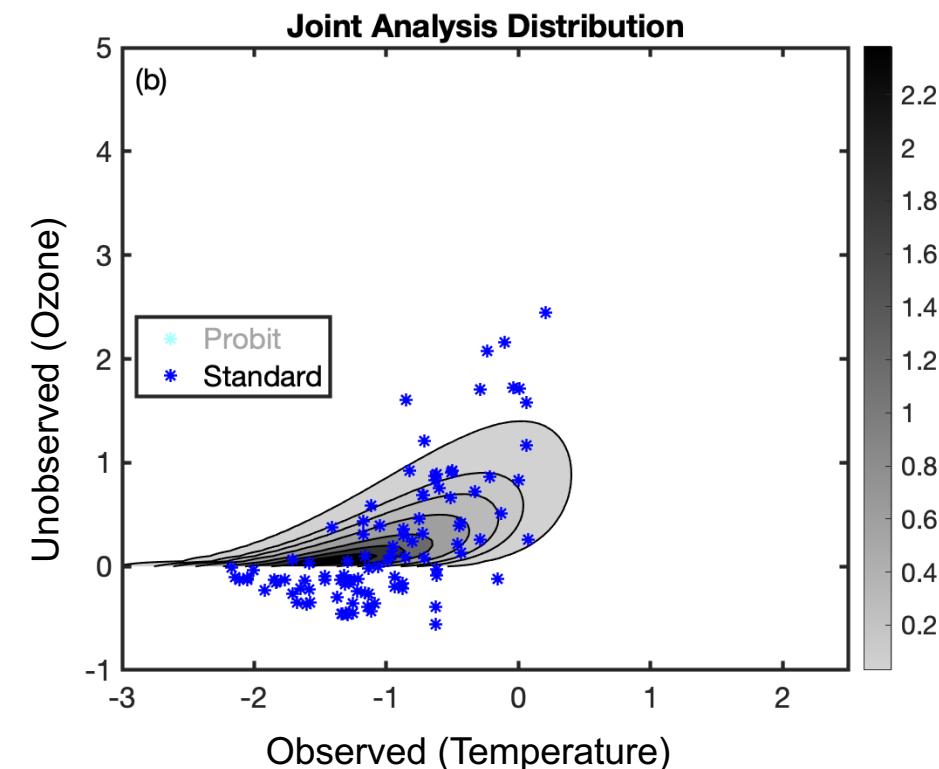

Correct distribution contours are 1, 5, 10, 20, 40, 60, 80% of max for all figures.

# Standard EAKF: Challenged by Non-Gaussian and Nonlinear Relations

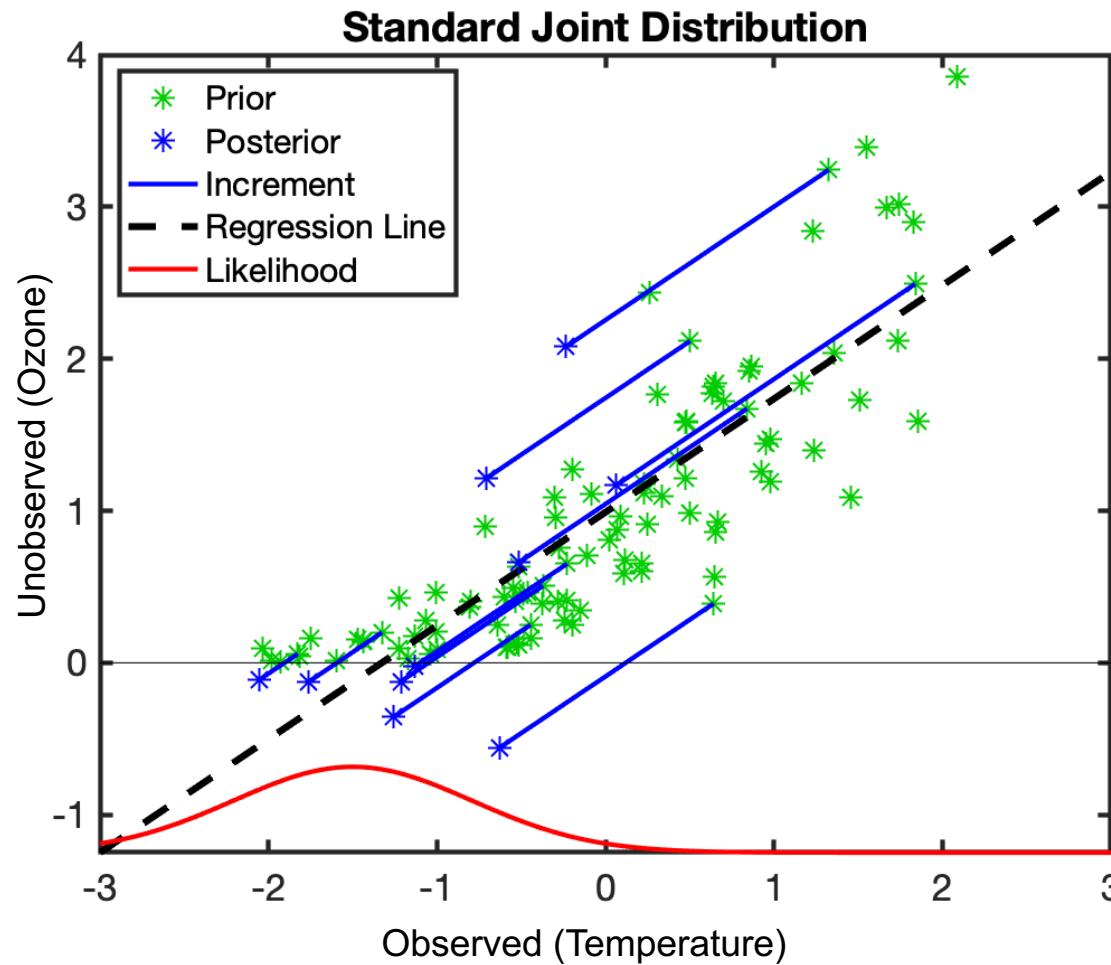

Prior for normal-gamma distribution with 100 member ensemble.

Posterior ensemble has problems.

# Standard EAKF: Challenged by Non-Gaussian and Nonlinear Relations

Example regression increment vectors:  
Don't respect bounds,  
Struggle with nonlinearity.

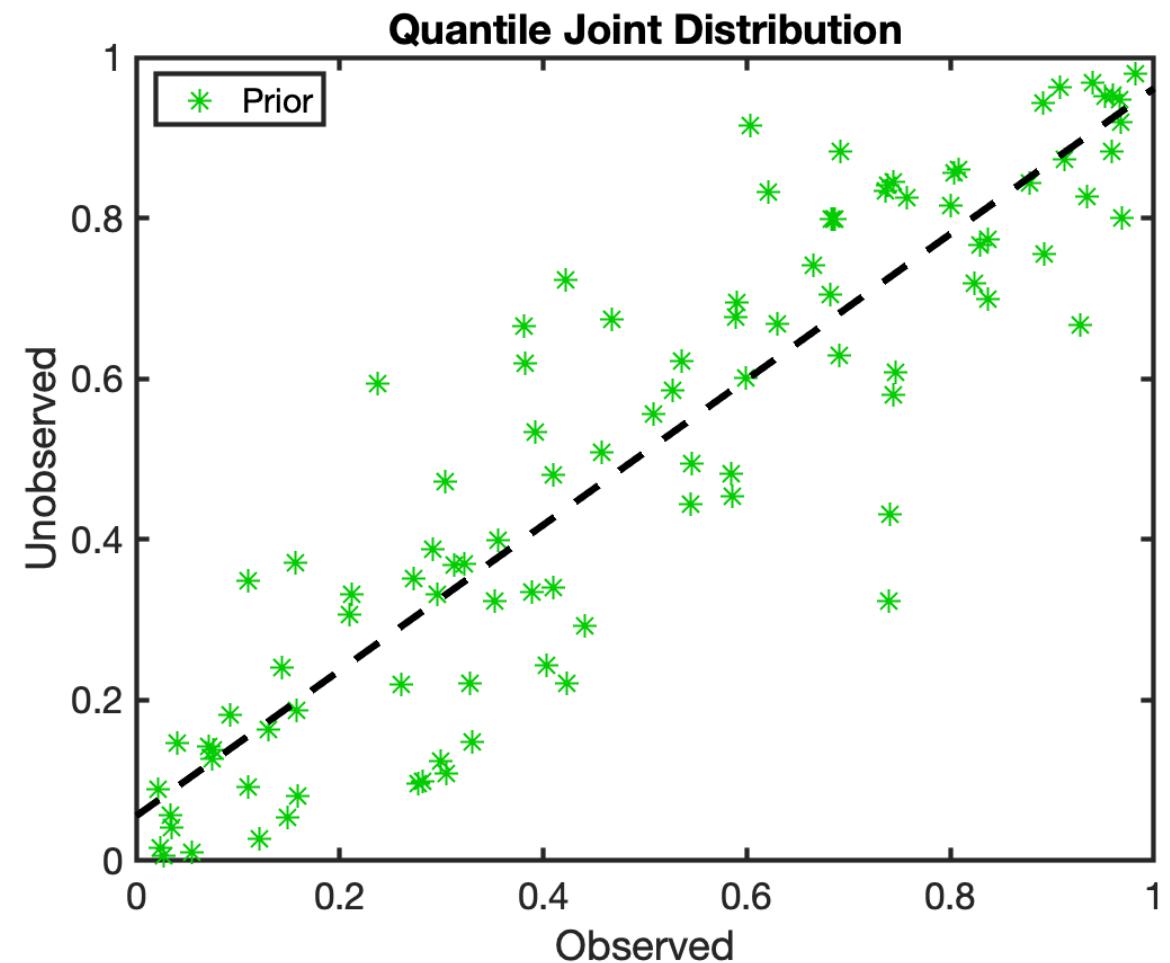

# Solution, Transform Marginals: Step 1: Compute Quantiles

Pick an appropriate continuous prior distribution.

Compute CDF for each member to get quantiles.

Quantiles are  $U(0, 1)$  for appropriate prior.

This is the probability integral transform.

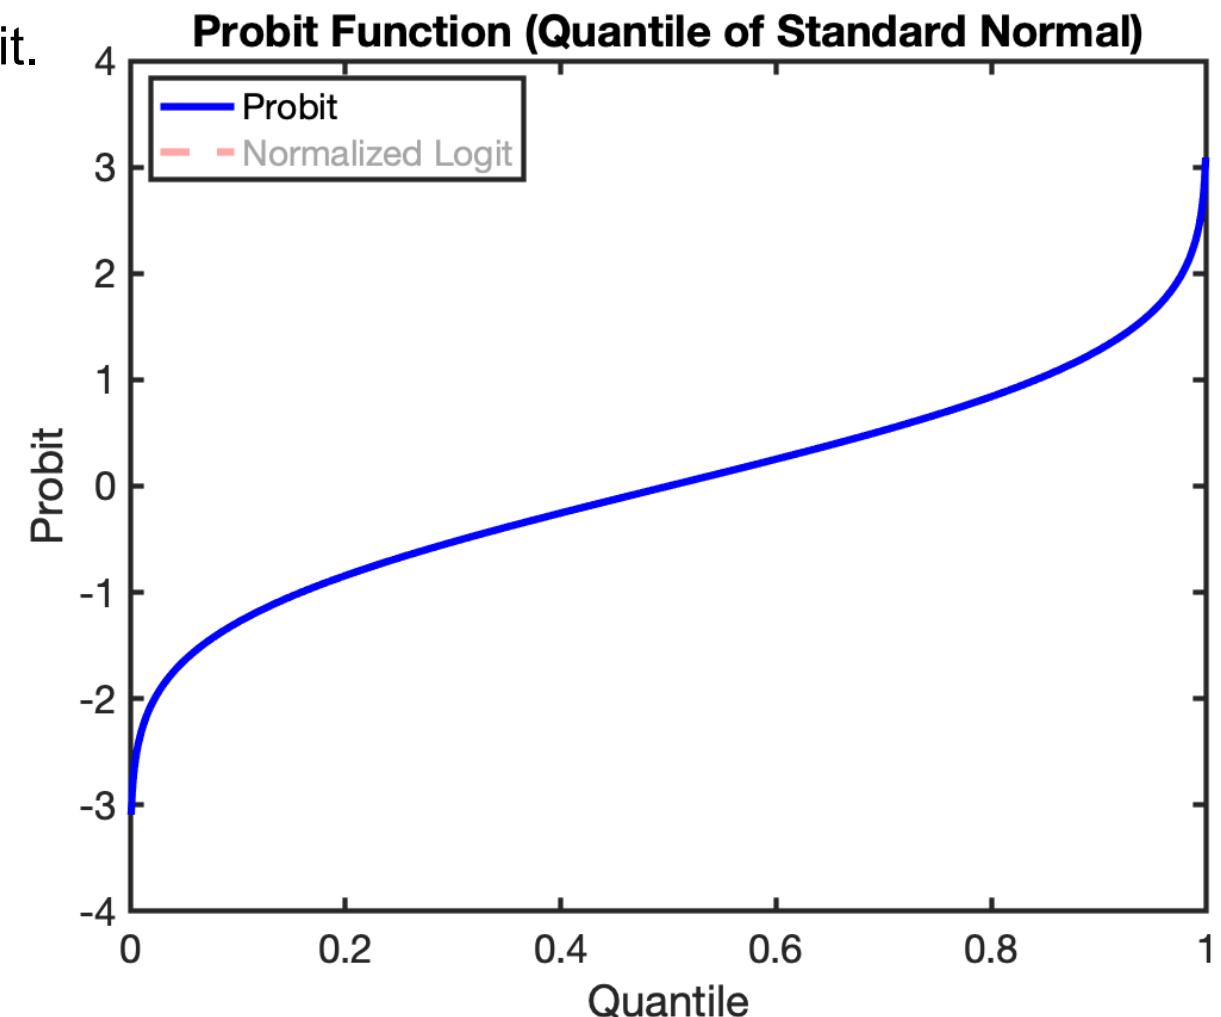

# Solution, Transform Marginals: Step 2: Probit Transform of Quantiles

Quantile function for the standard Normal is probit.

Transforms  $U(0, 1)$  to unbounded.

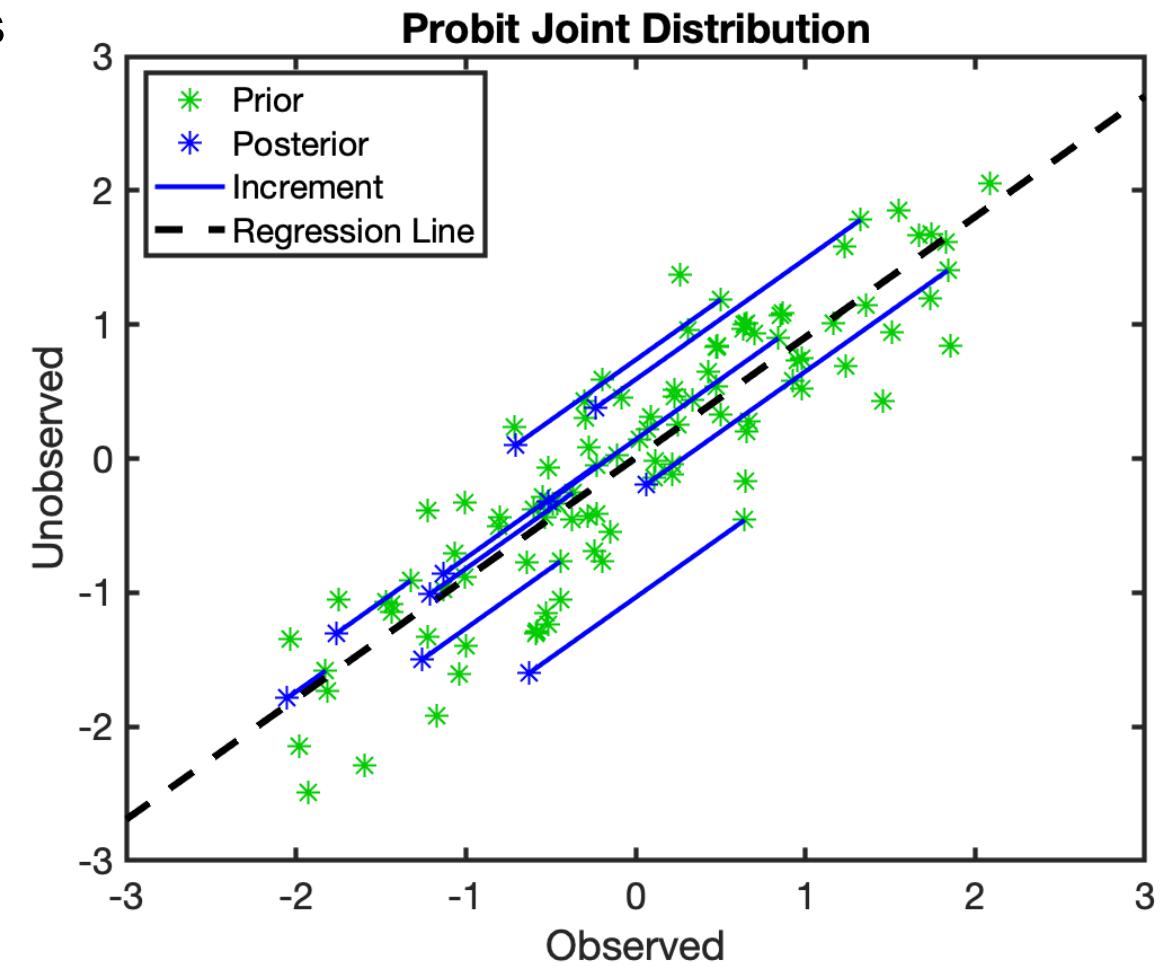

Marginal distributions should be  $N(0, 1)$ .

# Regression in Probit-Transformed Quantile Space

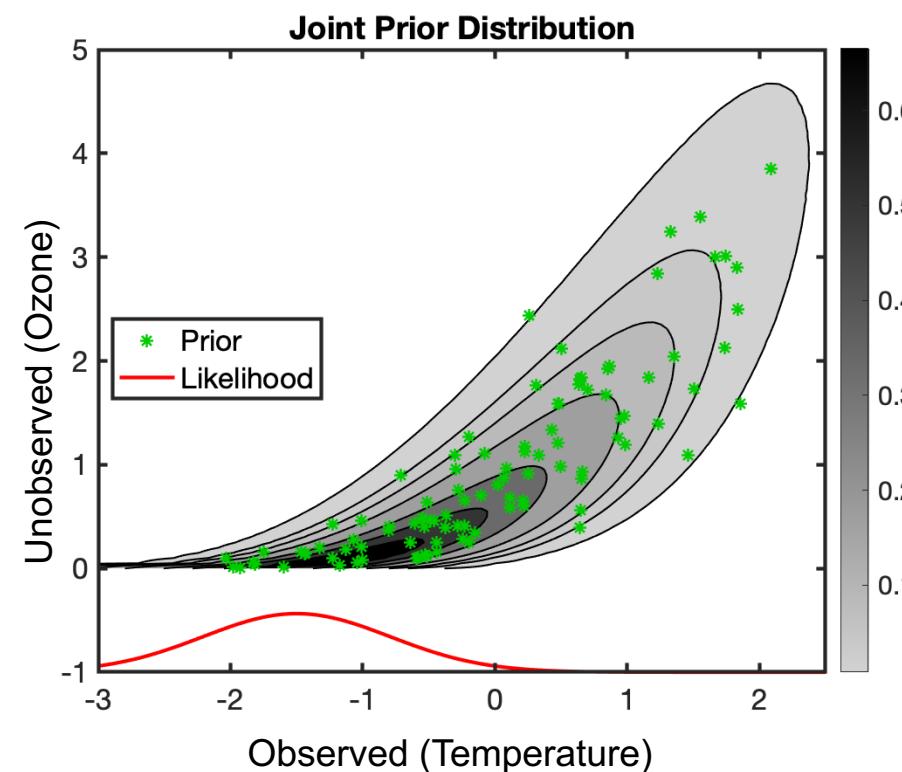

Do the regression of the observed probit increments onto the unobserved probit ensemble.

Linear regression is best unbiased linear estimator (BLUE) in this space.

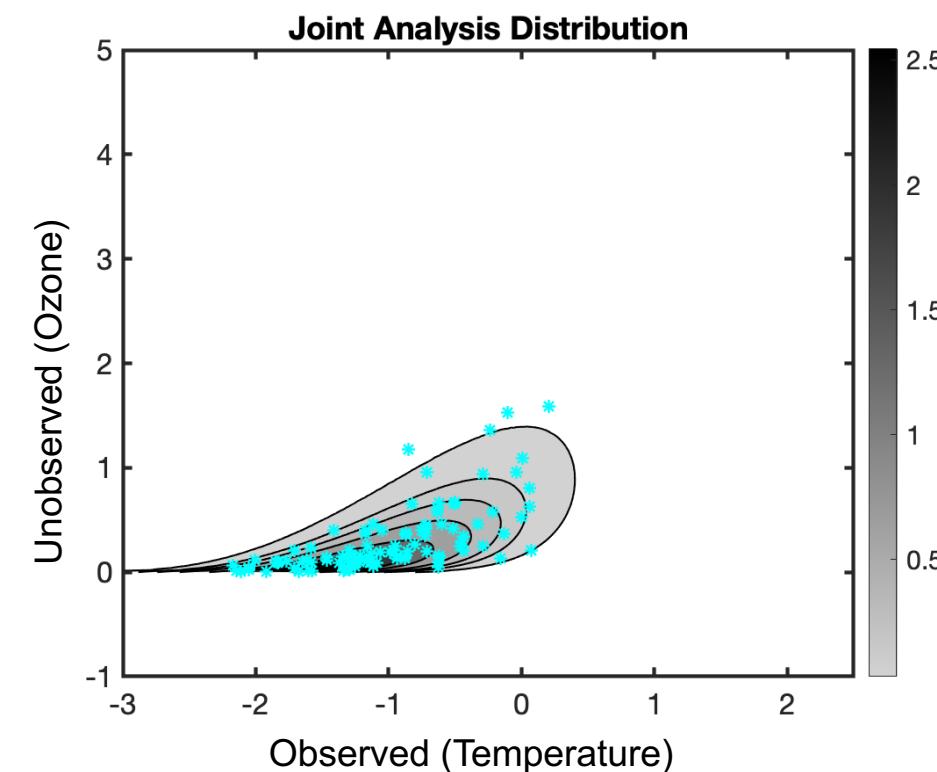

# DART: Novel, General Solutions for Nonlinear, Non-Gaussian Problems

Prior for normal-gamma distribution with 100 member ensemble.

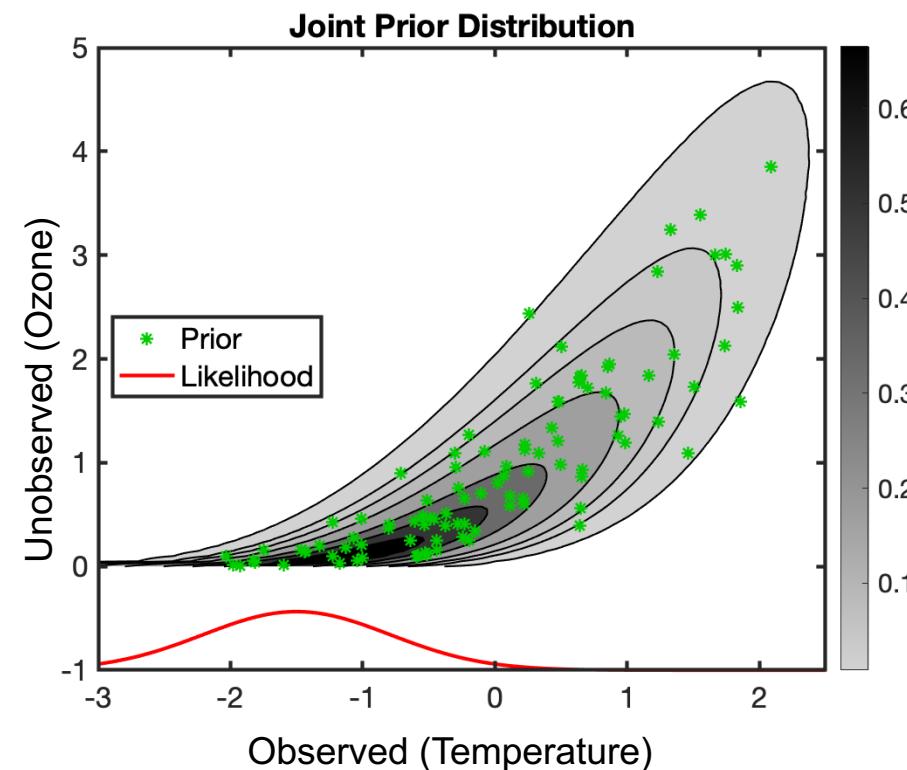

Bounds enforced. Nonlinear aspect respected.

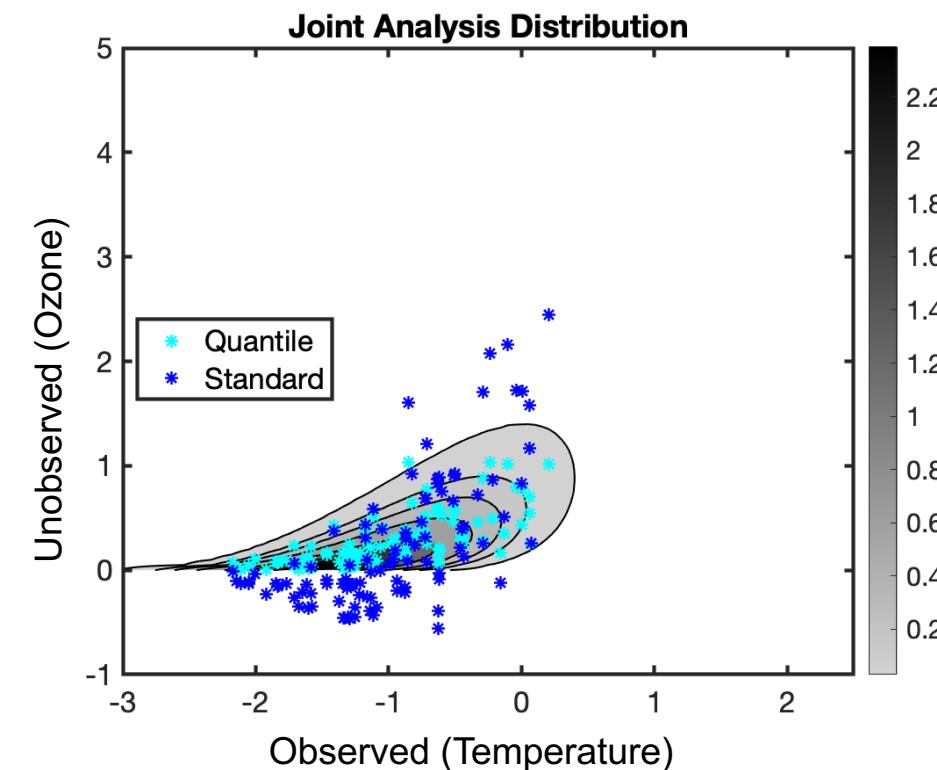

# DART: Novel, General Solutions for Nonlinear, Non-Gaussian Problems

Prior for normal-gamma distribution with 100 member ensemble.

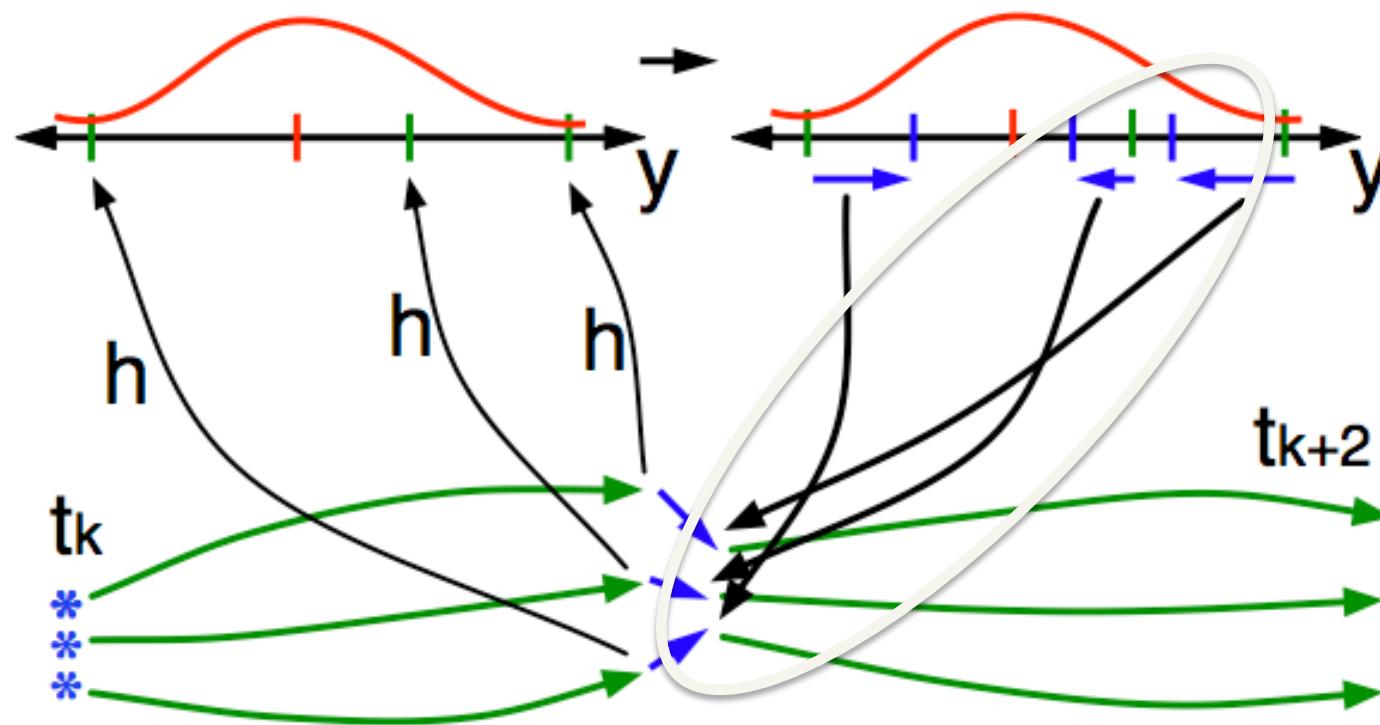

Bounds enforced. Nonlinear aspect respected.

# DART Now Implements Regression in a Transformed Space

Can update unobserved variables with regression in a transformed space for each state variable.

(Anderson, 2023, MWR151, 2759-2777)

# Regression in Probit-Transformed Quantile Space

$y_n^p, y_n^a, x_n^p, n=1, \dots N$  are prior and posterior (analysis) ensembles of observed variable y and unobserved variable x.

$F_x^p$  and  $F_y^p$  are continuous CDFs appropriate for x and y.

$\Phi(z)$  is the CDF of the standard normal,  $\Phi^{-1}(p)$  is the probit function.

$\tilde{x}_n^p = \Phi^{-1}[F_x^p(x_n^p)]$ ,  $\tilde{y}_n^p = \Phi^{-1}[F_y^p(y_n^p)]$  and  $\tilde{y}_n^a = \Phi^{-1}[F_y^p(y_n^a)]$  are probit space.

$\Delta\tilde{y}_n = \tilde{y}_n^a - \tilde{y}_n^p$  is probit space observation increment.

$\Delta\tilde{x}_n = \frac{\tilde{\sigma}_{x,y}}{\tilde{\sigma}_{y,y}} \Delta\tilde{y}_n$  regress increments in probit space (eq. 5 Anderson 2003).

$\tilde{x}_n^a = \tilde{x}_n^p + \Delta\tilde{x}_n$  is posterior ensemble in probit space.

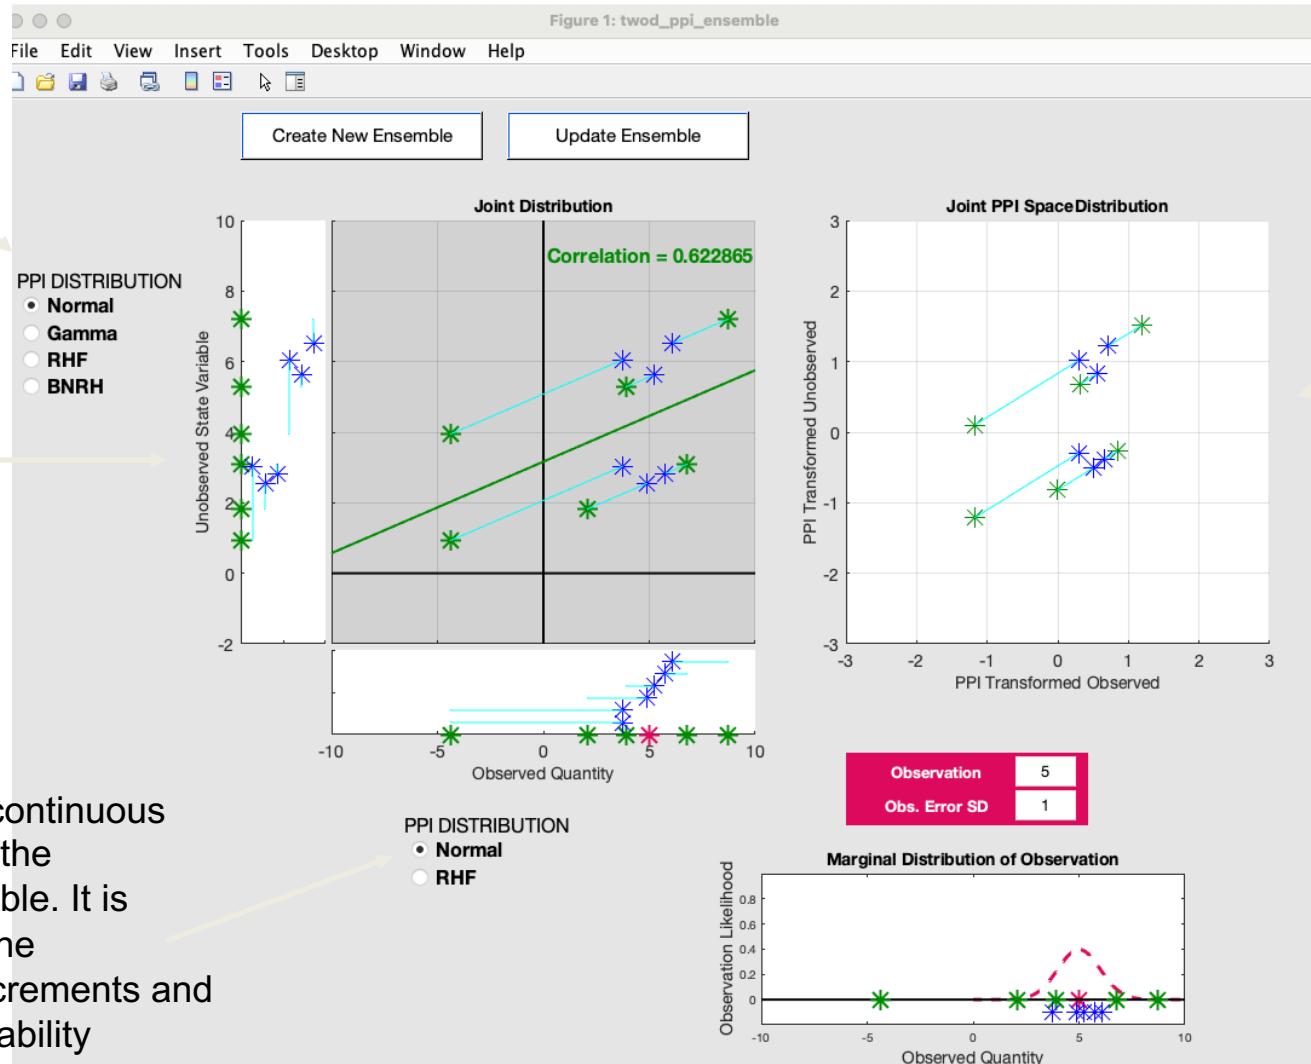

$x_n^a = (F_x^p)^{-1}[\Phi(\tilde{x}_n^a)]$  is posterior ensemble.

# Matlab Hands-on: twod\_ppi\_ensemble

For the unobserved variable, select the distribution for the probit probability integral transform.

This plot is similar to twod\_ensemble except that the unobserved variable is nonnegative.

Select from a continuous distribution for the observed variable. It is used both for the observation increments and the probit probability integral transform.

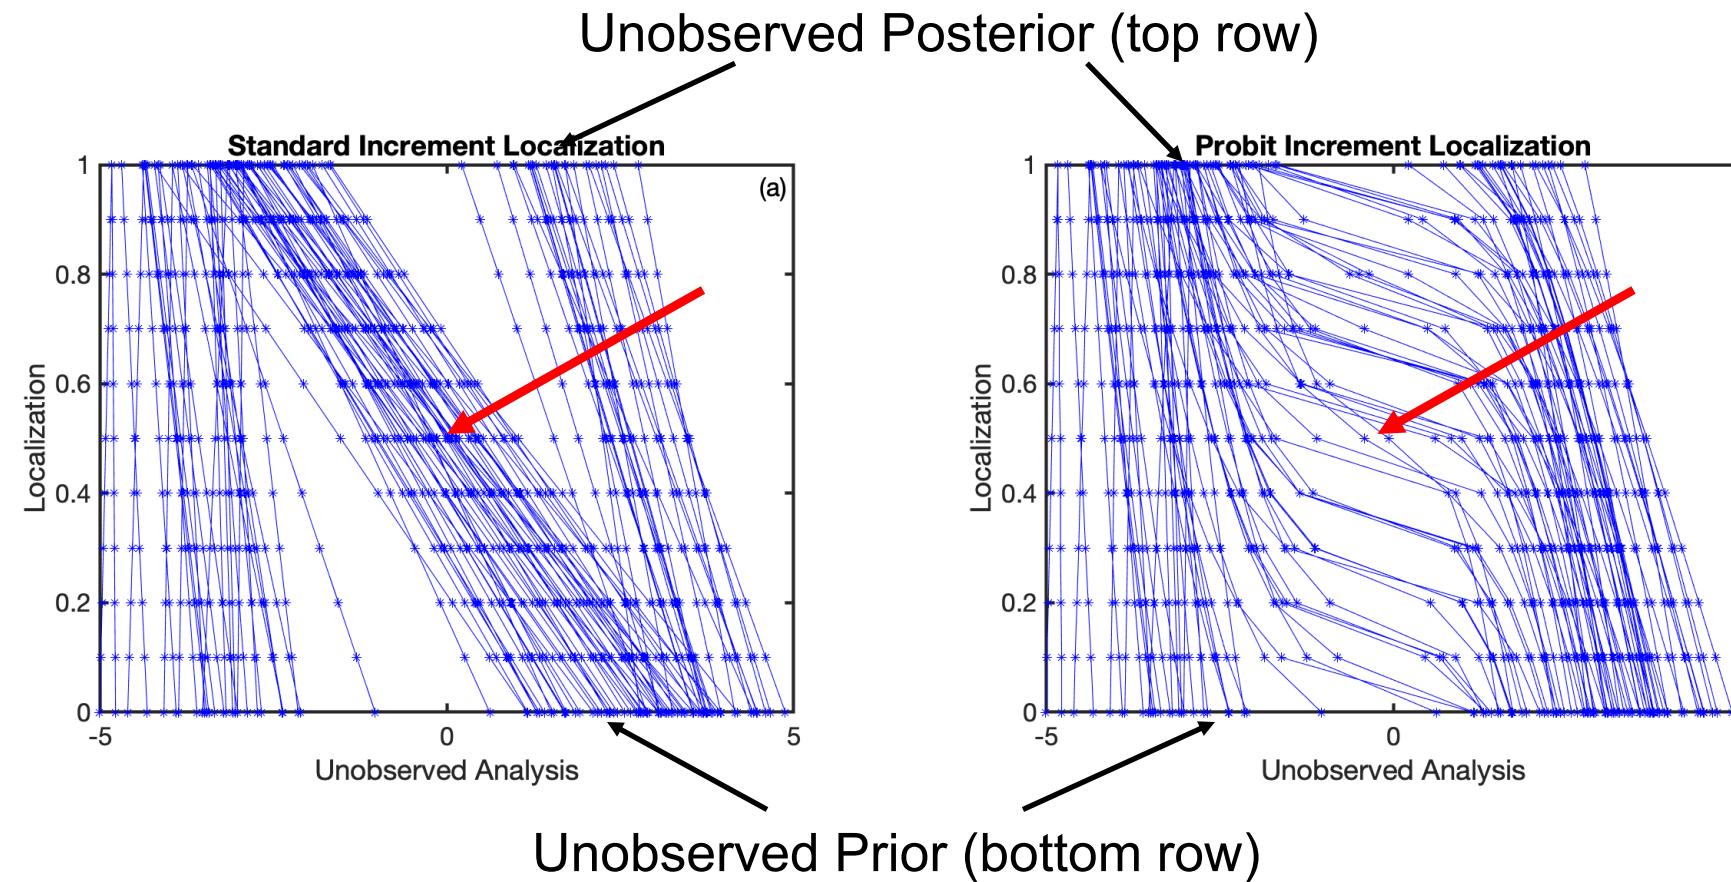

This panel shows the prior and posterior in the probit probability integral transformed space.

Try to create a case with negative posterior members for the unobserved variable.

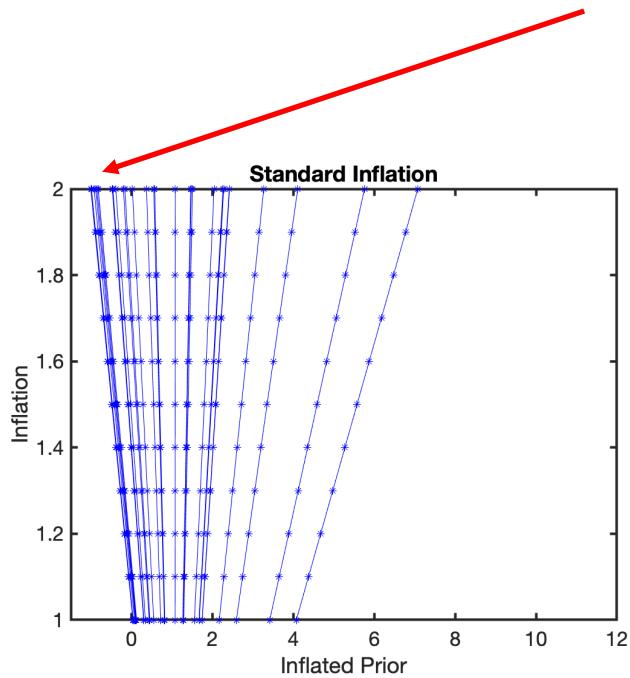

# Localization of Probit Increments: Normal-binormal example

Standard increment localization may ignore prior constraints.  
Probit increment localization ‘knows’ prior was binormal.

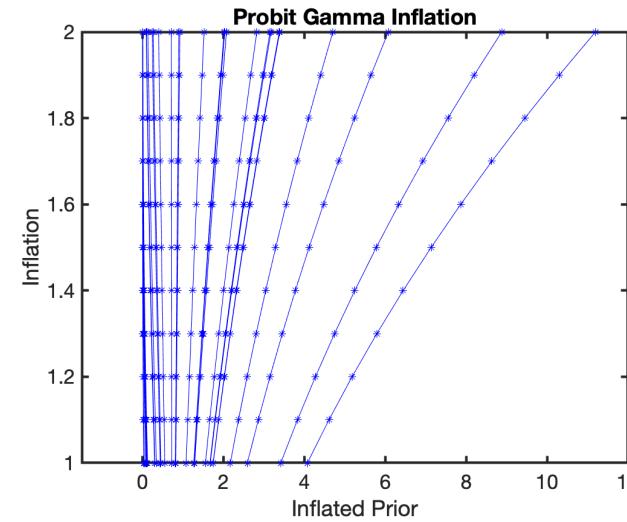

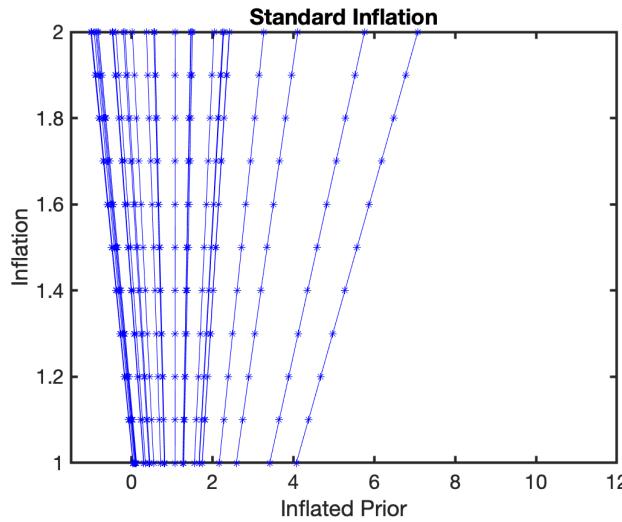

# Inflation in Probit Space: Gamma example

Standard inflation may violate prior constraints.

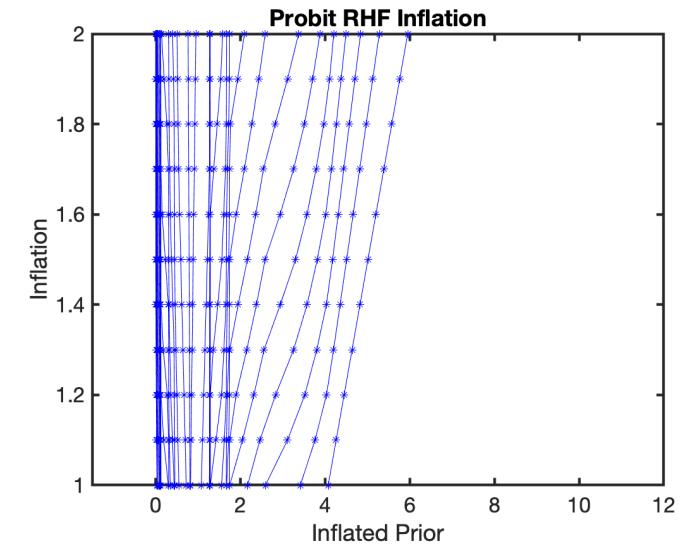

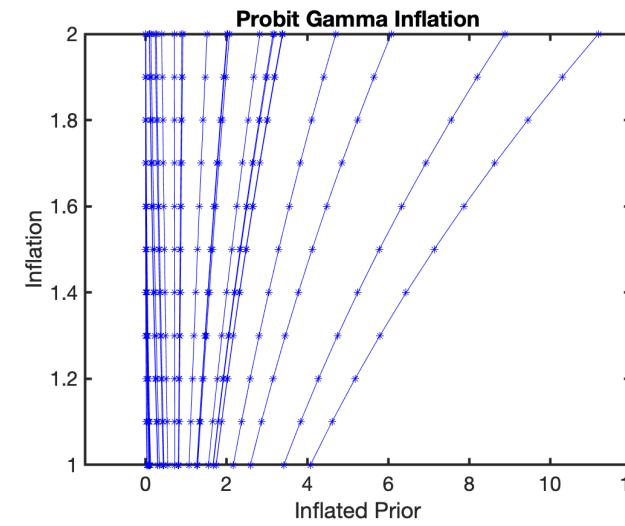

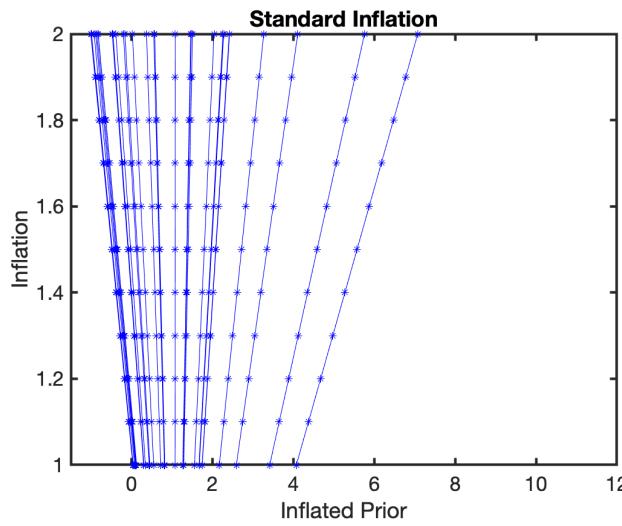

# Inflation in Probit Space: Gamma example

Standard inflation may violate prior constraints.  
Inflation can be done in probit space.

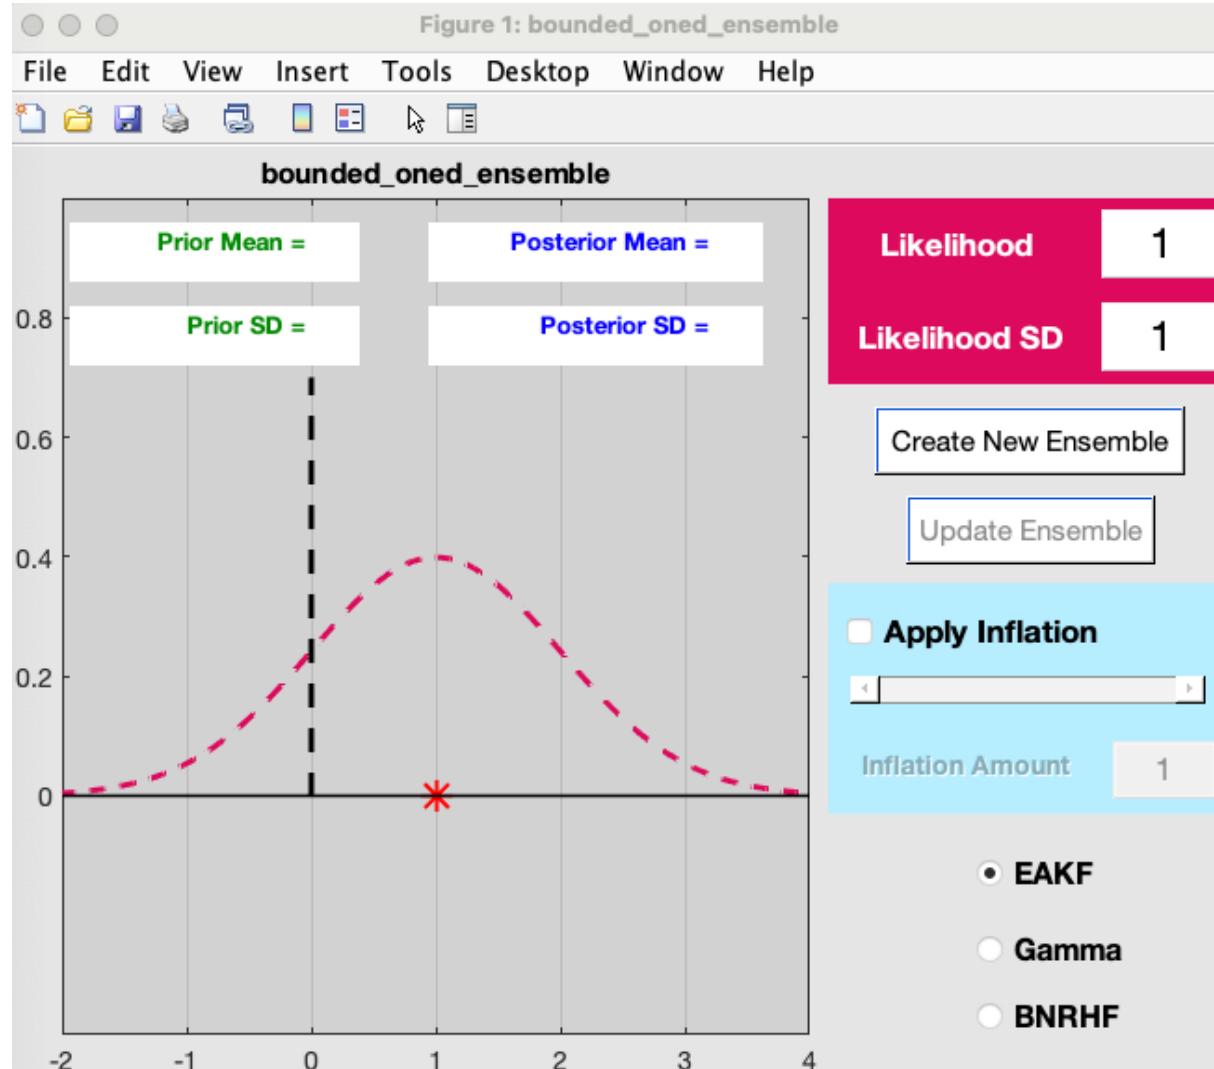

# Inflation in Probit Space: Gamma example

Standard inflation may violate prior constraints.  
Inflation can be done in probit space. And with BNRH!

# Matlab Hands-on: bounded\_oned\_ensemble (2)

Try applying inflation with the different continuous priors.

# What about the normal-normal case?

Computing increments in regular space is equivalent to computing increments in probit space.

Recall that the QCEFF normal filter in observation space is equivalent to the traditional EAKF in observation space.

Similarly, the method here is identical to the EAKF for unobserved updates.

The EAKF is equivalent to the Kalman Filter for normal/normal cases.

The QCEFF normal combined with probit space regression here is an ensemble generalization of the EAKF and the Kalman filter.
